

### **Test 1**

The well was opened through a 3.2 mm (8/64") adjustable choke and later increased to a 6.4 mm (16/64") choke. During the 8 hours flow period the surface production rate was 2 Sm<sup>3</sup>/D. In order to increase the production rate, the string contents (water) were reversed out and displaced with diesel, thereby reducing the weight of the string contents. The well was opened on a 7.9 mm (20/64") choke. The production rate was not improved. After 15 minutes the well was shut in. When reversing out the diesel some hydrocarbon gas (C1, C2 and C3) was detected on the mudlogging system. The pressure and rate measurements from test 1 are presented in fig. 5.2.

### **Test 2**

Test 2 was cancelled due to the results of test 1. However, a cased hole RFT was run in order to identify the fluid system.

The cased hole RFT sample from 3972 mRKB (depth reference final print CN/DEN/GR log, run 5B) contained primarily mud, cement water and traces of gas. A pressure point was also taken at 3978 mRKB. The pressures are presented in section 5.3.

### **Test 3A**

The well was opened on 6.4 mm (16/64") adjustable choke. The choke size was stepwise increased to 31.8 mm (80/64"). After the production of one string volume (28 m<sup>3</sup>), small amounts of waxy oil was produced with formation water. An average total rate (oil and water) of 19 Sm<sup>3</sup>/D was measured on the tank during this last period. The BS&W measurements on the well stream showed a watercut of 90 - 97%. The pressure and rate measurements from test 3A are presented in fig. 5.3.

### **Test 3B**

The second interval was perforated with wireline guns, and an immediate pressure increase followed. The well was opened on 4.8 mm (12/64") adjustable choke. The choke was then stepwise increased to 16.7 mm (42/64"). A water rate of 610 Sm<sup>3</sup>/D was registered. No oil was produced during Test 3B. H<sub>2</sub>S was measured on Dräger tubes and consequently the test was stopped and the well was killed. The pressure and rate measurements from test 3B are presented in fig. 5.3.

Further details, test interpretation and fluid analyses will be given in Saga's Well Test Report 6406/11-1S.

## 5.5 Fluid Analyses

### FMT samples

During the formation pressure measurements, three segregated samples were taken. The FMT-sample from 3694.3 mRKB contained oil and water. Analyses were carried out on the oil showing a waxy oil with a pour point of 34° C. The PVT analyses of the oil gave a bubble point pressure of 275 bar at 80° C and a stock tank oil density of 875.4 kg/m<sup>3</sup>. The GOR from single stage flash is 126.5 Sm<sup>3</sup>/Sm<sup>3</sup>. The reservoir oil composition is given in fig. 5.4.

### Test 1

During test 1 in the Åre Formation minor amounts of water was produced. This was not enough to perform analyses.

### Test 2

The cased hole RFT sample from 3972 mRKB (depth reference final print CN/DEN/GR log, run 5B) contained primarily mud and cement water. Some gas was sampled when flashing the one gallon chambre contents to standard conditions. The gas was analysed, and heptanes and lighter components were found. H<sub>2</sub>S was not detected. The analysed gas sample was mixed with air.

### Test 3A

During the first part of test 3A, the initial string contents were produced. After the production of one string volume (28 m<sup>3</sup>), small amounts of waxy oil was produced with the water. Stock tank oil samples were taken, and a total wax contents of 31 weight% is measured in the laboratory.

### Test 3B

Due to the short production of test 3B, clean formation water was not obtained at the end of the production period. The well was killed because of H<sub>2</sub>S detection. A gas sample collected at wellhead was analysed one month later; H<sub>2</sub>S was then not detected, but Carbonyl Sulfide (COS) at 4.1 ppm was measured.

**INTRODUCTION**

Geochemical analyses were performed on 70 cuttings samples, 11 core-chip samples, 10 sidewall core samples and 2 oil samples from the well NOCS 6406/11-1S (approximate location - Figure 1-map). The analyses were performed according to the analytical program ordered by Saga Petroleum and was as follows:

Lithology description	94 samples
Headspace/occluded gas analysis	69 samples
TOC by LECO carbon analyser	36 samples
Whole rock pyrolysis using Rock-Eval	32 samples
Extraction, separation and asphaltene precipitation of soluble bitumen of whole rock samples	15 samples
Capillary - gas chromatography of saturated and aromatic hydrocarbon fractions	12 samples
Gas chromatography - mass spectrometry	11 samples
$\delta^{13}\text{C}$ isotope analysis of C <sub>1</sub> - C <sub>4</sub> gases	10 samples
$\delta^{13}\text{C}$ isotope analysis (saturated HC, aromatic HC, NSO and asphaltene fractions)	11 samples
Vitrinite reflectance microscopy	38 samples
Visual kerogen microscopy	8 samples
Complete oil analysis	2 samples

Tables listing in detail which samples were analysed and with all data acquired from individual geochemical analyses are located in Appendix 1. Saturated and aromatic hydrocarbon gas chromatograms are in Appendix 2. Reflectance histograms are in Appendix 3. Gas chromatography - mass spectrometry fragmentograms are in Appendix 4.

**FLUID ANALYSIS****Oil Analysis Results**

	<u>Gravity</u>	<u>Sulphur</u>	<u>Ni(mg/l)</u>	<u>V(mg/l)</u>
		<u>Content</u>		
DST 3A	884.9 kg/m <sup>3</sup>	0.07	> 0.3	> 0.3
DST 3A,>210°C fraction	887.0 kg/m <sup>3</sup>			

**Comments**

The sample was so viscous that it required warming to 60°C several times in order that it could be transferred to suitable sample vessels for the different analyses. This could have affected the gravity measurement.

**Procedure**

Gravity was measured at 15°C. The instrument used was an AP Paar Density meter.

Sulphur was measured using a Princeton Gamma Tech. The blank standard was "babyoil".

Nickel and vanadium were analysed using an IPC AES, using a 1:10 dilution with p.a. quality kerosene.

## EXPERIMENTAL PROCEDURES

### Headspace gas analysis

The analysis is performed using a gas chromatograph with a 50 m capillary column, loop injector and flame ionisation detector. Helium is used as carrier gas.

Two cm<sup>3</sup> of headspace gas are removed from each sample can for chromatographic analysis of the C<sub>1</sub> to C<sub>7</sub> range of hydrocarbons.

### Occluded gas analysis

The analysis is performed using a gas chromatograph with a 50 m capillary column, loop injector and flame ionisation detector. Helium is used as carrier gas.

The canned samples are washed in thermostatted water to remove drilling contaminants and sieved on a 2 mm mesh sieve to remove large, caved rock fragments. An aliquot (ca 25 mg) of sieved sample is crushed with 25 cm<sup>3</sup> water in an airtight ball mill. After crushing, 2 cm<sup>3</sup> of the released gas are removed from the ball mill for gas chromatographic analysis.

### Total organic carbon (TOC) and total carbon analysis

This analysis is performed using a LECO CS244 Carbon Analyser.

Hand-picked lithologies from cutting samples are crushed with a mortar and pestle and approximately 200 mg (50 mg for coals) are accurately weighed into LECO crucibles. The samples are then treated three times with dilute hydrochloric acid, to remove oxidised (carbonate) carbon, and

washed four times with distilled water. The samples are dried on a hotplate at 60-70°C before analysis of total organic carbon. Total carbon is analysed on the same instrument using approximately 200 mg of untreated crushed whole rock. Oxidised (carbonate) carbon is calculated by difference.

#### Extractable Organic Matter (EOM) Analysis

Samples are selected for extraction on the basis of screening analysis. 10 - 20 g of whole rock are accurately weighed.

Extraction is carried out in a Tecator Soxtec HT extractor using 7% (v/v) methanol in dichloromethane as extraction solvent. Samples are boiled for 1 h and rinsed for 2 h. Samples with TOC greater than 10% are extracted a second time and the extracts combined. After filtration into a tared flask the solvent is removed by rotary evaporation at 200 mB and 35°C. The residue, dried to constant weight, is weighed to give the amount of EOM.

#### Separation of Asphaltenes

The EOM is dissolved in 1:3 (w:v) tetrahydrofuran in an tared flask and pentane added to precipitate asphaltenes. A minimum of 40 volumes of pentane per 1 volume of THF/EOM is used and the solution allowed to stand 8 h at room temperature in the dark. The solution is filtered and the precipitated asphaltenes returned to the original flask by dissolution in methanol (7% v/v)/dichloromethane. The asphaltene solution is evaporated to constant weight.

Liquid chromatographic separation

Chromatographic separation is performed using an MPLC system developed by the company. The EOM (after removal of asphaltenes) is injected into the MPLC and chromatographed using hexane as eluent. This effects a separation into saturated and aromatic fractions which are collected and concentrated on a rotary evaporator, at 35°C and 200 mB, to remove the bulk of the hexane. The fractions are then transferred to small tared vials and evaporated to dryness in a stream of nitrogen. The vials are re-weighed to obtain the weights of both fractions. The weight of the NSO fraction, which is retained on the chromatography column, is obtained by difference.

Gas chromatographic analyses**Saturated fraction**

The instrument used for this analysis is a gas chromatograph with a 25 m OV1 column, split injector and FID detector. The carrier gas is helium and the temperature program runs isothermally at 60°C, for 2 minutes and then rises to 290°C at a rate of 4°C/min.

The sample of saturated fraction is diluted by 1:20 with hexane and a 1 microlitre aliquot of this is injected into the instrument.

**Aromatic fraction**

The instrument used is a gas chromatograph with a 25 m SE-54 capillary column, split injector and effluent splitter leading to FID and FPD detectors, allowing simultaneous analysis of hydrocarbons and sulphur compounds. The carrier

gas is helium and the temperature program runs from 60°C to 300°C at a rate of 4°C/min.

The sample of aromatic fraction is diluted by 1:20 with hexane and a 1 microlitre aliquot of this is injected into the instrument.

#### Whole Oil

Whole oil chromatograms are determined on a gas chromatograph fitted with a split injector, 25m SE54 capillary column and effluent splitter connected to FID and sulphur mode FPD detectors allowing simultaneous determination of hydrocarbons and sulphur compounds. Approximately 0.1 microlitres of whole oil are injected and the temperature program on the chromatograph runs from -10°C to 300°C at 4°C/min.

#### Rock Eval pyrolysis

This analysis is performed using a ROCK EVAL II Pyrolyser into which approximately 100 mg of crushed whole rock are loaded. Analysis involves heating the sample, from 300°C to 600°C, in an inert atmosphere (helium) to release naturally generated hydrocarbons (S1 peak) and then pyrolytically generated hydrocarbons (S2 peak), both of which are detected by an FID. In the temperature interval between 300°C and 390°C, the released gases are split and a proportion passed through a carbon dioxide trap, which is connected to a thermal conductivity detector (TCD). The value obtained from the TCD corresponds to the amount of oxygen contained in the kerogen of the sample and is reported as the S3 peak. The temperature corresponding to the maximum of the S<sub>2</sub> peak, T<sub>max</sub>, is also recorded.

Thermal extraction/pyrolysis gas chromatography

The instrument used for this analysis is a gas chromatograph connected to a pyrolysis oven. A very small amount ( 2 mg) of whole rock sample is loaded into the oven and heated isothermally, at 300°C, for 3 minutes, during which time thermal extraction of the generated hydrocarbons occurs (equivalent to the S1 peak of Rock Eval). The released gases pass to a 15 m OV1 column with a nitrogen-cooled trap.

After 3 minutes the pyrolysis oven heats up to 510°C, at a rate of 40°C per minute, causing bound hydrocarbons to be released from the kerogen of the sample (equivalent to the S2 peak of Rock Eval). These gases are passed through a 25m DB1 capillary column with a nitrogen-cooled trap.

The temperature program for the chromatographic oven, in which both columns are situated, rises from 0°C to 290°C at a rate of 4°C/min. Both columns are linked to FID detectors.

Vitrinite reflectance analysis

Samples, in the form of small granules, are mounted in a

fast setting resin. The resin blocks are ground on coarse corundum paper to expose the rock granule surfaces and then on three finer grades of corundum paper to improve these surfaces and reduce scratches. The resin blocks are finally polished on a rotating Selvyt-covered lap using two grades of polishing alumina. Isopropyl alcohol is used to lubricate the entire grinding and polishing process except in the case of coal samples, when water is used.

Reflectance measurements are taken under oil immersion ( $n = 1.518$ ) using a ZEISS MPM03 microscope photometer with a 546nm interference filter. The polished blocks are mounted on the microscope stage and scanned manually in order to locate and measure particles of vitrinite. An attempt is made to obtain readings from 20 individual particles per sample but this is not always possible in samples with low amounts of phytoclasts.

Spore fluorescence colour

Samples are also analysed microscopically in U.V. light, using an exciter filter with a band pass of 400 - 440 nm and a barrier filter with a long pass of 470 nm, and the colour of the spore fluorescence is determined. This is used as an alternative maturity parameter to verify the result obtained from vitrinite reflectance and is reported on a numerical scale from 1 to 9:

Fluorescence Colour	Colour Index	Corresp. Vitrinite Reflectance
Green	1	0.2%
Green/Yellow	2	0.2/0.3%
Yellow	3	0.3%
Yellow/Orange	4	0.4%
Light Orange	5	0.5%
Mid-Orange	6	0.6%
Dark Orange	7	0.8%
Orange/Red	8	1.0%
Red	9	1.1%

NB. This table only provides a rough correlation as vitrinite reflectance and spore fluorescence colour are both independently affected by factors such as depositional environment and catagenic history.

Preparation of Kerogen Concentrates

Samples are stirred for 16 h with 25 cm<sup>3</sup> concentrated hydrochloric acid at 35 - 40°C. The acid is decanted and the residue washed by stirring for 3 h with 25 cm<sup>3</sup> distilled water. The washing is repeated twice more.

If the concentrate is not being prepared for slides the residue is washed, rapidly, at this point, with 25 cm<sup>3</sup> dichloromethane.

25 cm<sup>3</sup> hydrofluoric acid are then added to the residue and the mixture stirred for 16 h at room temperature. The acid is decanted and the residue washed by stirring for 3 h with distilled water. The water washing is repeated three times with fresh aliquots of distilled water each time. The water is then decanted and the residue either dried in an oven at 40 - 50°C to constant weight, or, if slides are to be made, it is transferred to a microscope cover slip and dried on a hot bench at 40 - 50°C.

Preparation of Slides

The dry kerogen concentrate is mounted on a slide in glycerine/gelatine and left to dry at room temperature overnight.

**EXPERIMENTAL****Isotope Ratio Mass Spectrometry**

The isotope analysis were performed on a dual inlet VG SIRA 10 instrument. The combustion of the samples were done by a Carlo Erba EA 1108 element analyser directly connected to the inlet system of the mass spectrometer.

The combustion temperature was 1020°C and the carries gas used was Helium. After the combustion H<sub>2</sub>O and CO<sub>2</sub> were trapped in different cool traps. The CO<sub>2</sub> gas was then heated up before it was admitted to the mass spectrometer. The whole operation was controlled by a IBM PC50 computer system.

**δ-values**

The isotope ratios are given as δ-values in ‰ versus the PDB-standard:

$$\delta^{13}\text{C} = (\text{R sample} - \text{R standard} / \text{R standard}) * 1000$$

$$\text{R} = ^{13}\text{C} / ^{12}\text{C}$$

The PDB standard (a marine chalk of the Pee Dee-formation, USA) was created by Craig 1957. All results of <sup>13</sup>C / <sup>12</sup>C - analysis of organic matter today are calculated (Craig correction) against this international standard.

**Reproducibility**

The presision of the combustion system and the mass spectrometer is controlled by determinations of an international calibrated standard, NBS22 oil and a house standard of carbon.

Double analysis on samples are also done.

Experimental, combined gas chromatography - mass spectrometry (GC-MS)

The GC-MS analyses were performed on a VG TS250 system interfaced to a Hewlett Packard 5890 gas chromatograph. The GC was fitted with a fused silica SE 54 capillary column (50 m x 0.22 mm i.d.) directly into the ion source. Helium (12psi) was used as carrier gas and the injections were performed in splitless mode. The GC oven was programmed from 45°C to 150°C at 35°C/min at which point the programme rate was 2°C/min. up to 310°C where the column was held isothermally for 15 min. For the aromatic hydrocarbons, the GC oven was programmed from 50°C to 310°C at 5°C/min and held isothermally at 310°C for 15 min. The mass spectrometer was operated in electron impact (EI) mode at 70 eV electron energy, a trap current of 500 uA and a source temperature of 220°C. The instrument resolution used was 1500 (10% valley).

The data system used was a VG PDP11/73 system. The samples were analysed in multiple ion detection mode (MID) at a scan cycle time of approximately 1,1 sec.

Calculation of peak ratios was done from peak heights in the appropriate mass fragmentograms.

In the discussion of the GC-MS data, the results will be discussed by area. The wells within an area will be discussed separately. In the discussion, samples within one formation are discussed together. The discussion is further divided into types of compounds as follows:

Saturated Fractions:

**Terpanes**

The most commonly used fragment ions for detection of terpanes are M/Z 163 for detection of 25, 28, 30 trisnor-morethane or 25, 28, 30 trisnorhopane, M/Z 177 for detection of demethylated hopanes or morethanes, M/Z 191 for detection of tricyclic, tetracyclic- and pentacyclic terpanes and M/Z 205 for methylated hopanes or morethanes. The molecular ions M/Z 370 and 384 are also recorded for identification of C<sub>27</sub> and C<sub>28</sub> triterpanes respectively.

**Steranes**

The most commonly used fragment ions for detection of steranes are M/Z 149 to distinguish between 5  $\alpha$  and 5  $\beta$  steranes, M/Z 189 and 259 for detection of rearranged steranes, M/Z 217 for detection of rearranged and normal steranes and M/Z 218 for detection of 14 $\beta$  (H), 17 $\beta$  (H) steranes.

The M/Z 231 fragment ion is used to detect possible aromatic contamination of the saturated fraction. It is also used for detection of methyl steranes.

Aromatic Fractions:

## Alkyl-substituted Benzenes

The M/Z 106 fragment ion is often used to detect the alkyl-substituted benzenes. It is especially useful for the detection of di-substituted benzenes. M/Z 134 can also be used for the detection of C<sub>4</sub>-alkylbenzenes, but benzothiophene will also give a signal with this fragment ion.

## Naphthalenes

Methylnaphthalenes are normally detected by the M/Z 142 fragment ion while C<sub>2</sub>-naphthalenes are detected by M/Z 156 and C<sub>3</sub>-naphthalenes by M/Z 170.

## Benzothiophenes and Dibenzothiophenes

Benzothiophene can be detected, as mentioned above, by M/Z 134. The M/Z 198 and M/Z 212 fragment ions are used for methylsubstituted dibenzothiophenes and dimethylsubstituted dibenzothiophenes respectively.

## Phenanthrenes

Phenanthrene is detected using the M/Z 178 fragment ion. Anthracene will, if present also give a signal in the M/Z 178 fragmentation. Methyl-substituted phenanthrenes give signals in the M/Z 192 fragment ion while the M/Z 206 fragment ion shows the dimethyl-substituted phenanthrenes and the M/Z 220 fragmentation shows the C<sub>3</sub> substituted phenanthrenes.

**Aromatic Steranes**

Monoaromatic steranes are detected using the M/Z 253 fragment ion while the triaromatic steranes are detected using the M/Z 231 fragmentation.
