Source rock analyses

SUMMARY

Nordland Group (323-1140m), Hordaland Group (1140-1673m), Rogaland Group (1673-1820m) (only analysed from 1000m as requested).

Fair to rich abundances of C₁-C₄ hydrocarbons. Upper Hordaland (1140-1320m) Group shows good source potential but is probably immature. Overall poor source potential. Geochemical zones A, B, C and D.

Shetland Group, 1820-2358m: Rich abundances of C₁-C₄ hydrocarbons below 1940m (richest zone 2093m to 2221m). Mature migrated hydrocarbons. Source potential of Shetland Group poor to fair. Zones E, F and G.

Cromer Knoll Group, 2358-2364m: Not analysed.

Dunlin Group, 2364-2414m: Fair source potential. Rich abundances of C₁-C₄ hydrocarbons. Mature migrated hydrocarbons. Zone H.

Statfjord Formation, 2414-2779m?: (Top Hegre not supplied by Saga).

Zone I. Poor source potential. Fair (rich in isolated samples) C₁-C₄ abundances.

Zone J, 2779-T.D.3416m: (Hegre Group?, Lower Statfjord Formation + Hegre Group?).

Poor source potential. Low abundance C₁-C₄ (probably indigenous).

INTRODUCTION

Cuttings samples between 1000m and T.D. (3416m) in well 34/7-3 have been analysed.

A total of 125 samples were supplied by Saga and as agreed (as for 34/7-1 and 34/7-2) alternate samples were analysed.

This report is an interpretation of the screening analyses requested ie. lithological description, total organic carbon and headspace and occluded gas analyses.

Formation tops were supplied to IKU by Saga as follows:

	<u>Depth (m)</u>
Nordland Group.	328m
Utsira Formation	990m
Miocene unconformity (Hordaland Group)	1140m
(Rogaland Group) Balder Formation	1673m
Shetland Group	1820m
Cromer Knoll Group	2358m
Dunlin Group	2364m
Statfjord Formation	2414m
Hegre Group	? (under drilling at time of enquiry).

As can be seen, the Upper and Middle Jurassic is absent in this well. On the basis of the screening analyses the well has been divided into 10 geochemical zones as follows:

- A: 990-1140m
- B: 1140-1320m
- C: 1320-1680m
- D: 1680-1820m
- E: 1820-1940m
- F: 1940-2275m
- G: 2275-2347m
- H: 2347-2401m

I: 2401-2779m

J: 2779-T.D. 3416m

(Last sample analysed 3409m.)

The relationship of these zones to the stratigraphy in this well is given in Table a.

It can be seen that with a few exceptions the geochemical zone boundaries correspond closely with the given stratigraphic boundaries. Some of the apparent discrepancy is caused by the sampling interval. The intersample distance being 10m and in this report 20m because every second sample has been analysed.

In this report the results of the analyses are discussed by geological formation with reference to the relevant geochemical zones. IKU were not given a top Hegre Group depth and we have tentatively suggested a boundary around 2779m. This is based purely on gas analyses and lithology and total organic carbon content and therefore may well be erroneous. This does not affect the validity of our interpretation of the geochemical data.

Table a. 34/7-3 (formation tops as supplied by Saga).

EXPERIMENTAL METHODS AND DESCRIPTION OF INTERPRETATION LEVELS

Gas analyses

A septum was attached to the can; a sample of the headspace gas was taken and analysed for C₁, C₂, C₃, i-C₄, nC₄ and C₅₊ (conditions: see below).

The can was opened, headspace volume, water volume and sample weight were measured. The canned samples were washed with temperated water on 4, 2 and 0.125 mm sieves to remove drilling mud and thereafter dried at 35°C.

For occluded gas analysis an aliquot of the 2-4 mm fraction of each sample before drying was crushed in water using an airtight ball mill. The evolved gas was analysed as described for headspace gas.

GC conditions:

C₁-C₅₊ analysis

This analysis was performed on Carlo Erba Fractovap 2150 and 2350 gas chromatographs equipped with 2m x 1/8" stainless steel columns filled with Porapack Q on Chromosorb using nitrogen as carrier gas. The oven temperature was 150°C. After elution of n-butane the column was back-flushed and C₅₊ was recorded. A standard gas containing methane, ethane, propane, n-butane, n-pentane and n-hexane was used for quantitation.

Lithological descriptions

Lithological examinations are normally carried out using a binocular microscope (maximum 50x magnification). Colour descriptions are in accordance with "Rock Colour Chart" published in 1979 by the Geology Society of America. Boulder, Colorado. The clients have a choice of three different levels of description from a simple identification of the lithologies to a full examination of the sample. Handpicking of the cuttings for organic geochemical analyses is based on these descriptions.

Total Organic Carbon

Bulk samples were crushed in a mortar. Aliquots of the samples were then weighed into Leco crucibles and treated three times with hot 10% HCl to remove carbonate, and washed 4 times with distilled water to remove traces of HCl. The crucibles were then placed on a hot plate and dried for 24 hours. The total organic carbon (TOC) content of the dried samples was determined using a Leco CR12 carbon analyser.

RESULTS

Results of the gas analyses

The tabulated results of headspace and occluded gas analyses can be found at the back of the report tables 1a, 1b and 1c. Table 1c is a combined headspace and occluded gas table and is mainly used in interpretation with some reference to the other tables where appropriate.

Nordland Group (328-1140m, Hordaland Group (1140-1673m, Rogaland Group (1673-1820m)

These groups correspond to geochemical zones A, B, C and D.

There is a variable abundance of gas in these samples. A zone of rich abundance of methane is found from 1000m-1400m below this from 1400-1660m there is a poor to fair abundance of C_1-C_4 hydrocarbons. This zone of poor gas abundance corresponds to the Hordaland Group below the Miocene unconformity. In the Balder Formation gas abundances are rich. In all of the Nordland Group samples methane is predominant however there is a noticeable increase in wetness in the lower Hordaland Group and Balder formation (wetness ranging from 4-6%). The abundances of butane and isobutane were too low to allow calculation of an iC_4/nC_4 ratio. The one value that has been calculated is relatively high and indicates immature gas, probably largely biogenic.

Shetland Group (1820-2358m)

This corresponds to geochemical zones e, f and g.

The low light hydrocarbon abundances for the top 2 samples analysed probably reflects caving from the overlying Balder formation. There is a very sharp and large increase in wetness from 1940m with an accompanying increase in total gas abundance. The wetness varies from 29%-86%. There is a zone of very high light hydrocarbon abundance from 2093m-2221m. This is also the zone of highest wetness. iC_4/nC_4 ratios indicate that the hydrocarbons present are mature. The gas data from the Shetland Group samples indicates the presence of mature migrated hydrocarbons. Presumably they are migrated as the lithology over this interval does not indicate a rich hydrocarbon potential and it would also be expected to be of relatively low maturity because of the shallow depth.

The lower part of the Shetland Group samples 2221-2347m show lower total abundances of C₁-C₄ hydrocarbons, although the wetness remains high (some samples show very poor abundances eg. B-8303, 2329m).

Cromer Knoll Group (2358-2364m)

No samples from this Group have been analysed.

Dunlin Group (2364-2414m)

The Dunlin Group samples show very rich abundances (comparable to the middle Shetland Group) of C₁-C₄ hydrocarbons. The wetness is higher than in the Shetland Group samples 86-92%. IC₄/nC₄ ratios indicate that the hydrocarbons are mature. The whole Dunlin Group as present in 34/7-3 (we have not received information on how much, if any, of it is missing in this well) shows a rich abundance of mature hydrocarbons. The maturity of the Dunlin Group samples is not yet known in this well. The described dominant lithology is a marl claystone of fair to good TOC content. If this is mature it may have contributed to the analysed hydrocarbons but it is likely that at least some of these hydrocarbons are migrated.

Statfjord Formation (2414m- (not given to IKU by Saga, but possibly around 2779m?))

Corresponds with geochemical zone i. The C₁-C₄ hydrocarbon abundances are very variable being mainly fair to good but with occasionally very rich values of the same order as those in the overlying Dunlin Group eg. samples B-8935, 2473m, B-8945, 2563m, B-8949, 2608m, B-8953, 2644m.

Zone J (Hegre Group?, Lower Statfjord and Hegre Group?) 2779m-T.D.

Below 2779m the abundance of C₁-C₄ hydrocarbons is poor and the wetness very low as the gas is predominantly methane. There is a zone from 3085m to 3211m where, although the total abundance is poor, the wetness is high. This may represent small amounts of indigenous hydrocarbons generated from mature kerogens or alternately small amounts of migrated hydrocarbons. Further analyses would be needed to establish which is the case.

Results of lithology and total organic carbon analyses

Nordland Group 328-1140m), Hordaland Group (1140-1673m), Rogaland Group (1673-1820)

Four lithological and TOC zones have been distinguished. Zone A 990-1140m covers the the Utsira Formation above the Miocene unconformity and is composed of light olive grey silty claystone with a fair TOC content (average 0.58%). Zone B 1140-1320m is within the Hordaland Group below the Miocene unconformity. This zone is characterised by a light olive grey calcareous claystone with average TOC contents 1.25% ie. a zone of good potential. Zone C 1320-1680m corresponds the lowest part of the Hordaland Group and consists predominantly of an olive grey - dark green grey claystone with poor TOC content (average TOC content 0.46%). Group D 1680-1820m corresponds to the Balder Formation and is characterised by a green grey - medium grey claystone with poor TOC content (lower than in the overlying Utsira Formation) average TOC content 0.32%.

In summary only zone B below the Miocene unconformity shows any source potential based on total organic carbon and although there is no data on maturity it is assumed to be immature. The rest of the samples show poor source potential.

Shetland Group (1820-2358m)

This group has been subdivided into three geochemical zones based on TOC and lithology: Zone E 1820m to 1940m. This zone is characterised by the appearance of a TOC poor, marl, light grey (av. TOC 0.33%). It corresponds to the upper part of the Shetland Group. Zone F, 1940-2275m. This zone is dominated by a medium grey claystone with a fair TOC content (av. TOC content = 0.80%). Zone G 2275-2347m corresponds to the lower part of the Shetland Group and consists mainly of medium grey calcareous claystone. The TOC content is lower than in the zone above (av. TOC = 0.54%). All of the zones in the Shetland Group show poor to fair hydrocarbon potential.

No samples were analysed from the Cromer Knoll Group (2358-2364m).

Dunlin Group (2364-2414m)

The Dunlin Group is not very thick in this well and relatively few samples have been analysed. The samples are dominated by a grey marl accompanied by variable amounts of sand or sandstone. The marl shows a fair TOC content (0.97%). It is not known which part of the Dunlin Group is 143/m/an1/10

present in 34/7-3. From these analyses the Dunlin Group in 34/7-3 shows only fair hydrocarbon potential.

* Statfjord Formation (2414-?2779m(?) Top Hegre not supplied to IKU)

The interval 2414m to 2779m however corresponds to IKU zone H. From 2414m to 2626m it consists mainly of varicoloured claystones with poor TOC contents. Below 2626m to 2779m sand and sandstone with minor claystone and coal from the dominant lithology. The coal may be an additive or may be in situ (Statfjord coal unit equivalent). Further analyses would be required to reveal its origin. The Statfjord Formation as analysed here shows poor hydrocarbon potential.

IKU zone J (2779-3409m, T.D. 3416m)

This zone may correspond to the Hegre Group or the sand (2779-2896m) may correspond to the lower Statfjord Formation and the sand, limestone and marl (2896m-T.D.) lithology to the Hegre Group. It is not possible to tell without further information. The entire zone shows poor TOC values (where measured) and is assessed as having poor hydrocarbon potential.

CONCLUSIONS

Nordland Group

This Group has been subdivided into 4 geochemical zones, A, B, C and D. Zones A, B and C Utsira Formation show variable abundances of C_1-C_4 hydrocarbons. Zone D corresponding to the Balder Formation show a rich abundance and increased wetness. Zone D may contain some migrated hydrocarbons. Those in the zones above are probably indigenous.

The Nordland Group has poor hydrocarbon potential except for the lower part of the Utsira Formation (Zone B 1140-1320m) which shows a fair to good potential.

Shetland Group (1820-2358m)

This has been subdivided into 3 geochemical zones based on differences in lithology and TOC. All zones show poor to fair hydrocarbon potential. Rich abundance of hydrocarbons present below 1940m. The high wetness and low iC_4/nC_4 ratio indicates mature hydrocarbons. Probably migrated hydrocarbons in view of the overall poor potential of the Shetland Group and its probable immaturity in this well. The zone of highest free hydrocarbon content is 2093-2221m.

Cromer Knoll Group (2358-2364m)

Not analysed.

Dunlin Group (2364-2414m)

This corresponds to IKU zone H. The samples analysed indicate fair hydrocarbon potential. The zone is rich in C_1-C_4 hydrocarbons. The wetness and low iC_4/nC_4 ratio indicates that the hydrocarbons are from a mature source. The maturity of the Dunlin Group in this well is not known but is probably fairly low so the hydrocarbons present are probably migrated.

Statfjord Formation (2414m to ?2779m? Top Hegre Group not supplied by Saga)

This corresponds to IKU zone I. The whole zone shows poor source potential. C_1-C_4 hydrocarbon abundances are variable. Fair to rich. The rich values however are only in isolated samples.

Zone J (Hegre Group?) 2779m-T.D.

This zone may correspond to the lower Statfjord sand(2779-2896m) and

Hegre Group sand/marl/limestone (2896m-T.D.) IKU was not supplied with stratigraphic data for this interval. This zone is characterised by poor source potential and a low total abundance of C₁-C₄ hydrocarbons. The wetness (C₂-C₄ hydrocarbons) is fairly high indicating that the hydrocarbons are mature. Probably indigenous.

The conclusion presented here is based on gas analyses and total organic carbon analyses. A good TOC content will not necessarily mean a good hydrocarbon source. Further analysis to establish kerogen type and maturity will be necessary to assess the source potential of various horizons in 34/7-3 and the nature of the migrated hydrocarbons.

B-9053	3040-49	0.37	*80% <u>Claystone</u> , moderate brown, calcareous, grading into Marl 10% <u>Limestone</u> , white-pink 10% <u>Sand</u> , as above Sm.am. Steel	
B-9055	3058-67	0.17	*60% <u>Claystone</u> , moderate brown, calcareous, grading into Marl 20% <u>Sand/Sandstone</u> 10% <u>Limestone</u> , as above 10% Contaminants (Steel, drilling fluid deposits)	
B-9057	3076-3103	0.23	60% <u>Sand/Sandstone</u> , light grey-brown-clear, fine-coarse *30% <u>Claystone</u> , moderate brown, as above 10% <u>Limestone</u> , white-pink, partly argillaceous Sm.am. Steel	

Lithology and Total Organic Carbon measurements

TABLE NO.: 2.
WELL NO.: 34/7-3

Sample	Depth (m)	TOC	Lithology
B-9059	3094-3103		90% <u>Sand/Sandstone</u> , as above 10% <u>Limestone</u> , as above Sm.am. Claystone (moderate brown); Steel
B-9061	3112-21	0.39	70% <u>Sand/Sandstone</u> , as above *20% <u>Marl</u> , moderate brown 10% <u>Limestone</u> , white, light brown, partly argillaceous grading into Marl Sm.am. Claystone (moderate brown); Steel
B-9063	3130-39	0.33	70% <u>Sand/Sandstone</u> , as above 20% <u>Limestone</u> , white-pink, chalky *10% <u>Marl</u> , moderate brown
B-9065	3148-57	0.28	80% <u>Sand/Sandstone</u> , as above 10% <u>Limestone</u> , as above *10% <u>Marl</u> , moderate brown
B-9067	3166-75		90% <u>Sand/Sandstone</u> , as above 10% <u>Limestone</u> , as above Sm.am. Marl; Claystone (moderate brown)
B-9067	3184-93	0.29	60% <u>Sand/Sandstone</u> , as above 30% <u>Limestone</u> , white-pink-light brown, partly argillaceous *10% <u>Claystone</u> , moderate brown, calcareous, partly grading into Marl Sm.am. Marl Trace: Claystone (greenish grey); Coal
B-9071	3202-11		90% <u>Sand</u> , light grey-light brown-clear, fine-coarse 10% <u>Limestone</u> , as above Sm.am. Claystone (moderate brown)

Lithology and Total Organic Carbon measurements

TABLE NO.: 2.
WELL NO.: 34/7-3

Sample	Depth (m)	TOC	Lithology
B-9073	3220-29		100% <u>Sand</u> , as above Sm.am. Limestone; Claystone/Marl (moderate brown)
B-9075	3238-47		70% <u>Sand</u> , as above 30% <u>Limestone</u> , white, pink, light brown, partly argillaceous Sm.am. Claystone/Marl (moderate brown); Steel
B-9077	3256-65	0.23	70% <u>Sand</u> , as above 20% <u>Limestone</u> , as above *10% <u>Claystone</u> , moderate brown, occ. calcareous, grading to Marl Sm.am. Claystone (greenish grey)
B-9079	3274-83		80% <u>Sand/Sandstone</u> , as above 20% <u>Limestone</u> , as above Sm.am. Claystone/Marl (moderate brown); Steel
B-9081	3310-28	0.20	80% <u>Sand/Sandstone</u> , as above *10% <u>Claystone</u> , moderate brown, occ. calcareous grading to Marl 10% <u>Limestone</u> , as above Sm.am. Steel (abundant)
B-9083	3346-64	0.23	80% <u>Sand/Sandstone</u> , as above *10% <u>Claystone</u> , as above 10% <u>Limestone</u> , as above Sm.am. Claystone (greenish) grey; Steel
B-9085	3373-82		80% <u>Sand</u> , light grey-clear-(light brown), very fine-medium grained 20% <u>Limestone</u> , as above Sm.am. Claystone (moderate brown)

Lithology and Total Organic Carbon measurements

TABLE NO.: 2.
WELL NO.: 34/7-3

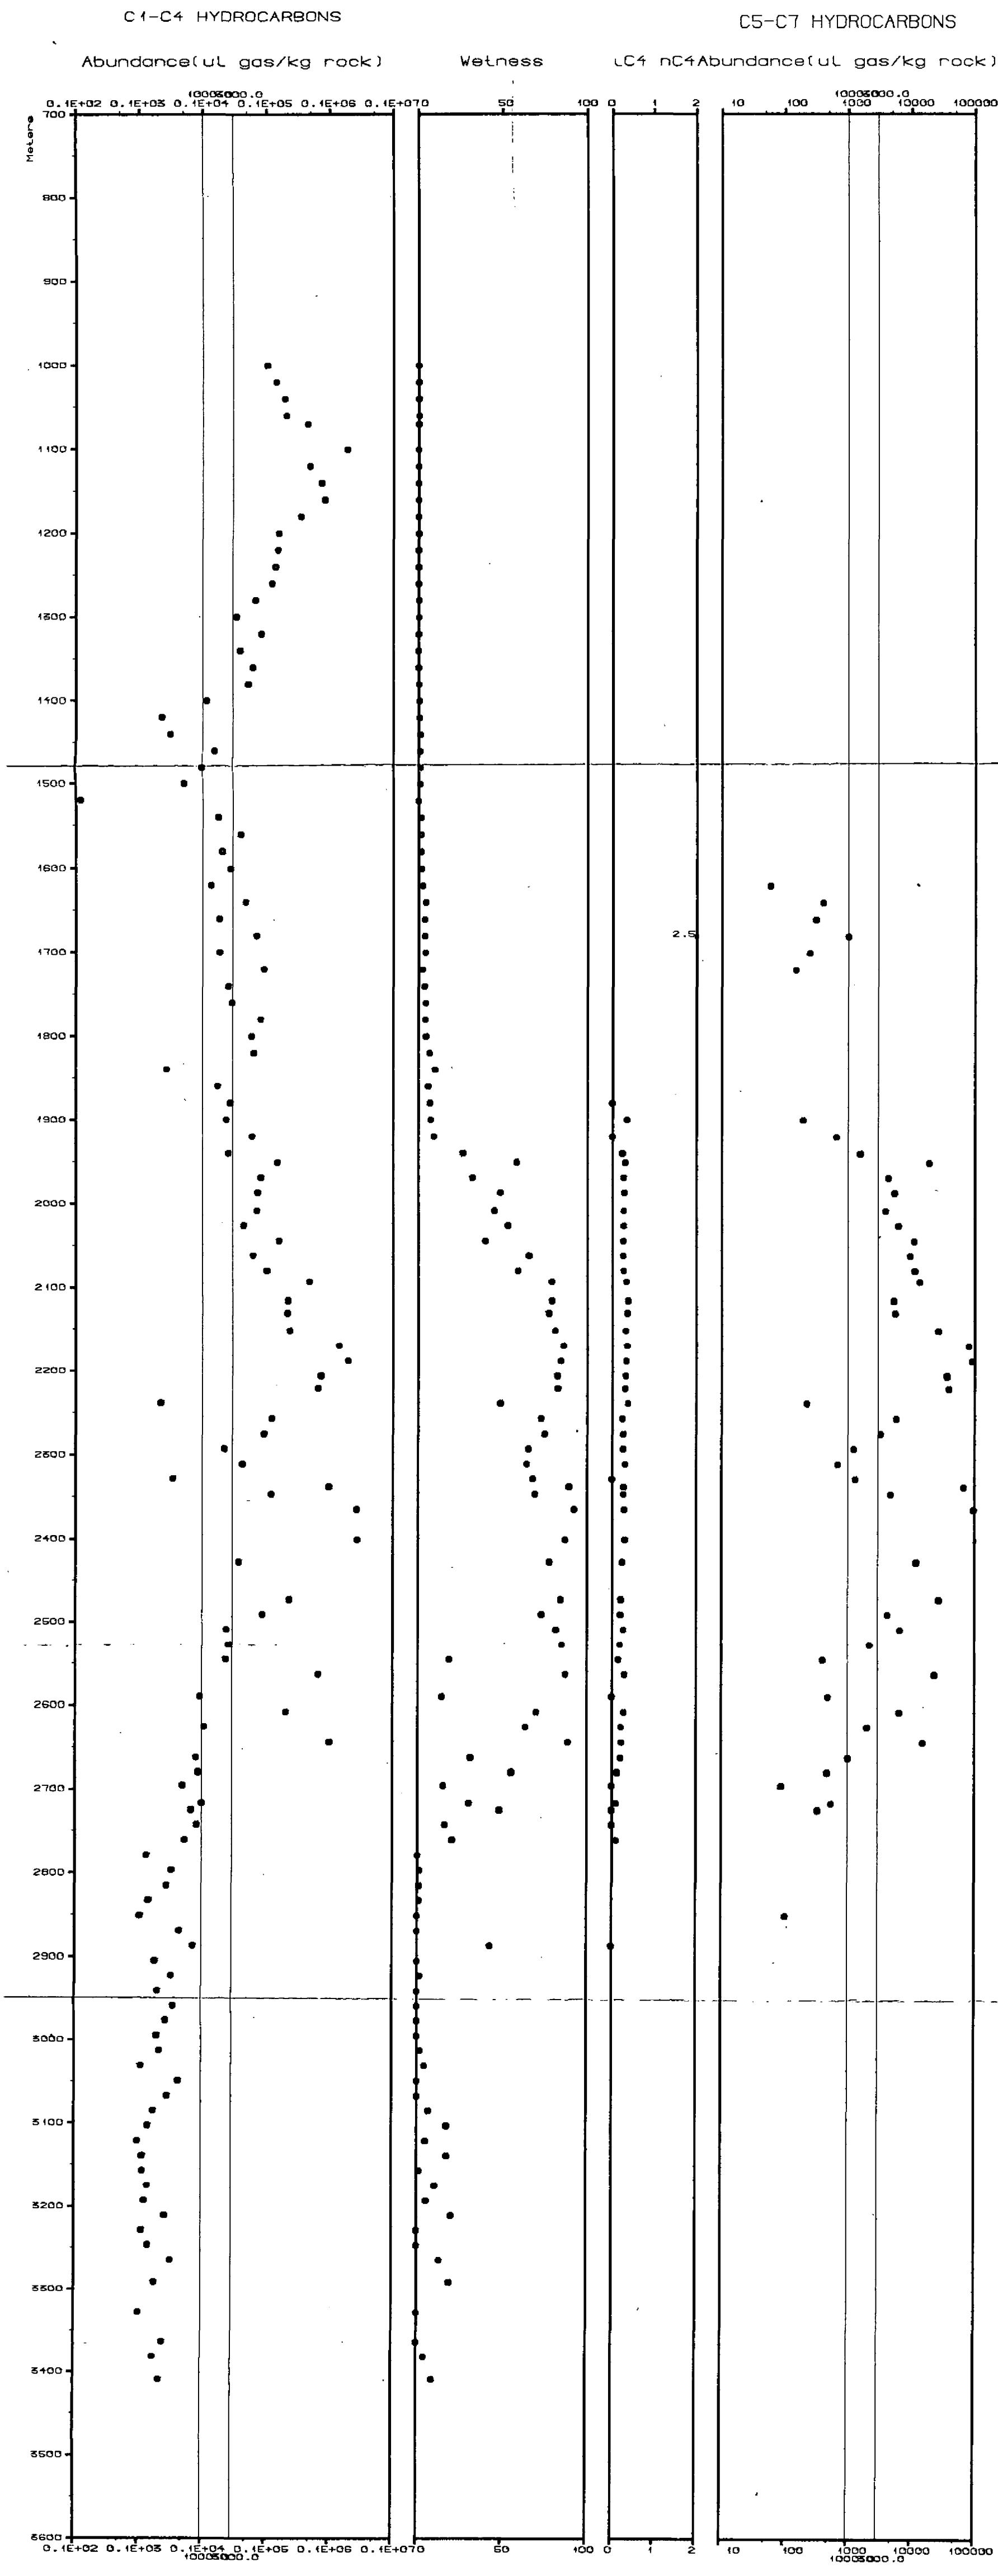

Sample	Depth (m)	TOC	Lithology
B-9087	3400-09	0.61	*40% <u>Claystone</u> , medium grey-greenish grey, micromicaceous. 40% <u>Limestone</u> , white, light grey 20% <u>Sand</u> , as above Sm.am. Claystone (moderate brown); Steel

34/7-3 WELL SUMMARY

UNIT	DEPTH	DEPTH	THICK.	REMARKS
	KB	SS	m	
Sea Bed	353	328	328	
Pliocene - Quaternary Nordland Gp.	353	328	637	
Miocene Utsira Fm.	990	965	150	
Eocene Oligocene Hordaland Gp.	1140	1115	532
