

5.4 Testing

One drill stem test was performed in the oilbearing section of the Statfjord Formation.

The test interval was

2547 - 2563 m RKB

(The depths refer to the CDL/CNL log of December 25, 1984).

The test objectives were to:

- sample reservoir fluid
- estimate reservoir pressure and temperature
- evaluate reservoir properties
- evaluate reservoir productivity
- confirm that no moveable water is present in the interval
- detect any lateral heterogenities in the sand

The main components in the test string were:

- A Geo Vann tubing conveyed perforating system
- One internal bundle carrier and one F-nipple in which the pressure temperature recorders were installed.
- A standard Halliburton DST-string with a downhole tester valve, circulating valves and a retrievable packer.
- 5" VAM-tubing 24.2 lbs/ft.
- A Flopetrol subsea test tree, lubricator valve and surface test tree.

A standard 1440 psi Flopetrol separator was used to separate gas and liquids.

The test zone was perforated against an open 19 mm adjustable choke at 70 bar underbalance to the formation. During the 10 minutes initial flow period 10.5m^3 of cushion were flowed back. The well was shut in for a 3 hours initial pressure build-up period to obtain

the initial pressure. The well was then opened for a 24 hours main flow period during which formation fluid was sampled at the wellhead and the separator. (see chapter 5.5 Fluid Analyses). Finally the well was shut in for a 36 hours main pressure build up period.

The main events of the test are listed in table 5.4. The flowrates and the bottom hole pressures are shown in fig. 5.2, and the pressure data from the last build up are listed in table 5.5.

During the main flow period the well produced clean oil at a rate of 865 Sm^3/day through a 9.5 mm fixed choke. The GOR was 34 Sm^3/Sm^3 at separator conditions of 19.5 bar and 14.4°C.

The maximum temperature recorded was 91°C.

The first hours of the flowperiod the choke plugged up repeatedly from coarse perforating debris, but after this clean-up period no water or sand was produced.

5.5 Fluid Analyses

Two FMT-chambers containing reservoir fluid were collected. These samples proved not to be representative, since the bubble point pressures were too low. Analyses of the fluid from these samples are presented in table 5.6.

Six single phase fluid samples were taken during the main flow period of the DST. This sampling was performed at the wellhead, since the pressure here exceeded the bubble point pressure of the fluid. In addition to this, Jerry cans of stabilized oil were filled from the separator outlet.

The final PVT-analyses report are not received to date, but preliminary data are presented in tables 5.7, 5.8 and 5.9.

The initial Formation Volume Factor was 1.27 m^3/Sm^3 and the Solution Gas Oil Ratio 73.5 Sm^3/Sm^3 . Both values are measured by single stage flash of reservoir fluid to standard conditions.
