WELL DATA

Operator : Den norske stats oljeselskap a.s

Well : 34/10-9

Location : 61°12'55.30" N  
              02°15'00.50" E

Classification : Exploration well

Rig : Ross Rig 24.3. - 9.5.80  
          Deep Sea Saga 29.5. - 3.7.80  
          ..(testing)

Spudded : 24 March 1980

Completed : 3 July 1980

RKB elevation : 25 m

Water depth : 203 m

Total depth : 2421 m RKB

Objective : Sandstone of middle jurassic age

Status : Plugged and abandoned

1. INTRODUCTION

Well 34/10-9 is the eighth well drilled on the Delta structure on Block 34/10. The well penetrated Brent, Dunlin and Statfjord formation, and reached a total depth of 2421 m RKB. Brent formation and Cook member of the Dunlin formation contained hydrocarbons. Statfjord formation contained water.

2. OBJECTIVES

The objectives of testing 34/10-9 were:

1. To test the Brent formation and the Cook member of the Dunlin formation for productivity, pressure and temperature.
2. To find the pressure profile in the Brent and Dunlin formation.
3. To obtain representative samples of the reservoir fluid.
4. To get an estimate of the fracture pressure in the Brent formation.
5. To estimate the OWC in the Cook member of the Dunlin formation.

--

3. CONCLUSIONS

1. RFT and DST data indicate that the Brent formation in well 34/10-9 represent the same pressure system as in previous drilled wells in the Brent formation. The gradient is 0.076 bar/m.
2. The data indicate that the Cook member of the Dunlin formation represent the same pressure system as in well 34/10-7 in the Cook member of the Dunlin formation. The gradient in the oil zone is 0.074 bar/m and 0.105 bar/m in the water zone.
3. The OWC in the Cook member of the Dunlin formation must be below - 2084 m MSL (below the tested interval during DST no. 1).
4. The permeability thickness of the tested part of the Brent formation is estimated to 100463 md'ft and the permeability to 362 md.
5. The DST no. 2 in the Cook formation indicate a high permeable zone at top of the formation. The permeability thickness is estimated to 85227 md'ft and the permeability to 2221 md.
6. The DST no. 1 was performed in a more shaly part of the Cook formation. The permeability thickness is estimated to 403 md'ft and the permeability to 17.6 md.
7. The fracture test indicate a fracturing pressure of 5562 psia at - 1857 m MSL (ie. equivalent mudweight 2.06 g/cc).
8. The fluid samples taken in the Brent and the Dunlin formation do not compare with samples from previous drilled wells on Delta.

9. The maximum temperatures recorded during the drill stem tests were:

84.4<sup>o</sup>C at - 2081 m MSL DST no. 1  
83.3<sup>o</sup>C at - 2962 m MSL DST no. 2A  
76.8<sup>o</sup>C at - 1882 m MSL DST no. 3

10. No water was produced during DST no. 2A and 3. During DST no. 1 very small amounts of water was observed in some samples.
11. The well did not produce sand, but small sand slugs was observed after choke changes during DST no. 2A and DST no. 3.

#### 4. DISCUSSION

##### 4.1 DST no. 1

The well was perforated in the Cook 2 member of the Dunlin formation from 2103 m RKB to 2109 m RKB. The tested part of the formation is shaly and a relative low permeability was expected. The log evaluation indicate a high water saturation (approx. 60%) in tested part of the formation. One of the objectives of the DST was therefore to examine the water production. But during the test only very small amounts of water was produced (0.2 - 0.3%). This could indicate a lower water saturation than estimated from logs.

The initial PBU was performed without problems, but during the final PBU the APR-N valve failed to close. The final PBU was therefore heavily influenced by wellbore storage.

###### 4.1.1 Analysis of DST no. 1

---

Because of the influence of the wellbore storage during the final build-up the test was to short to reach the Horner straight-line. The maximum slope method suggested by Raghavan and Rivery was used to analyse the PBU. The method is empirical and the results from the analysis must be considered as approximate values. The analysis indicate a permeability thickness of 403 md·ft and a permeability of 17.6 md.

The skin value is estimated to 33. The reservoir pressure calculated by this method is to low, the reservoir pressure estimated from the initial PBU, however, is close to the reservoir pressure calculated from the RFT data. The initial PBU indicate a reservoir pressure of 4820 psia at - 2062 m MSL.

A thickness of 7 m, an average porosity of 19% and a water saturation of 60% was used in the analysis. PVT properties were taken from the Core lab. report RFLA 80147 based on a sample taken during DST no. 2A.

The analysis of the DST can be found in appendix A1.

#### 4.2 DST no. 2 and 2A

The well was perforated in the Cook 3 member of the Dunlin formation from 2084 RKB to 2090 RKB. The interval tested is clean compared with the interval tested during DST no. 1. Therefore a higher permeability was expected.

The DST no. 2 was aborted due to plugging of the sandscreen. The test was renamed to DST no. 2A. The same interval was tested.

##### 4.2.1 Analysis of DST no. 2A

---

The test was analysed by using the Horner method. The analysis indicate a permeability thickness of 85227 md·ft, a permeability of 2221 md, and a skin factor of + 11.4. Because of the large perforated interval compared with the net pay, the total skin factor calculated is close to the formation skin factor.

The DST indicate a reservoir pressure of 4792 psia at - 2031.5 m MSL. This pressure is lower than indicated by the RFT data by within the accuracy of the tools.

A thickness of 11.7 m, an average porosity of 29% and a water saturation of 34% was used in the analysis. These data are estimated from the CPI log in appendix A8. PVT properties were taken from the Core lab. report RFLA 80147 based on a sample taken during the DST.

The analysis of the DST can be found in appendix A2.

4.3 DST no. 3

The well was perforated in the Rannoch member of the Brent formation from 1904 m RKB to 1910 m RKB.

4.3.1 Analysis of DST no. 3

---

The Horner method was used to analyse the DST. The analysis indicate a permeability thickness of 100464 md\*ft, a permeability of 362 and a total skin factor of + 10.6. The net pay thickness between 1854 m RKB and 1945 m RKB was used in the calculation of the permeability. The net pay thickness include the Rannoch member and the lower part of the Etive member of the Brent formation. The permeability of 362 md calculated from the DST data compare excellent with the permeability of 385 md estimated by log/core analysis. The calculated skin factors support the net pay thickness used in the analysis. The partial penetration skin factor is estimated to + 46, the total skin factor calculated from the DST data is + 10.6. This indicate a larger effective completion interval than perforated. The reason is probably poor cement bond and fluid flow in the annulus between the casing and the borehole.

The DST indicate a reservoir pressure of 4509 psia at - 1857 m MSL. This pressure compare excellent with the RFT data.

A thickness of 84.5 m, an average porosity of 30% and a water saturation of 17% was used in the analysis. These data are taken from the CPI log in appendix A8. PVT properties were taken from the Core lab. report RFLA 80146 based on a sample taken during the DST.

The analysis of the DST can be found in appendix A3.

#### 4.4 RFT analysis

The repeat formation tester was run and data were obtained from 1838 m RKB to 1875 m RKB in the Brent formation and from 2086 m RKB to 2131 m RKB in the Dunlin formation. Besides the repeat formation tests, two formation interval tests (FIT) were run in well 34/10-9. One test was performed in the Brent formation at 1840 m RKB. The sample contained hydrocarbons. The other test was performed in teh Cook member of the Dunlin formation at 2132 m RKB. The objective of this test was to examine the interval with regard to a later drill stem test. But the sample contained water and the DST no. 1 was performed above this interval.

From the RFT data, a gradient pf 0.074 bar/m is estimated in the Brent formation. The data compare well with data from the Brent formation in previous drilled wells on the Delta structure.

In the Cook member of the Dunlin formation the data collected compare well with the data from well 34/10-7 in the Dunlin and Statfjord formation. The data from 34/10-9 are scattered, but compared with the data from well 34/10-7 a gradient of 0.076 bar/m is estimated in the oil zone and a gradient of 0.105 bar/m is estimated in the water zone. Because of the scattered data the OWC is a subject to discussion. The data indicate an OWC between - 2080 m MSL and - 2100 m MSL.

#### 4.5 Reservoir temperature

The maximum recorded temperatures recorded during the drill stem tests were:

|                                     |            |
|-------------------------------------|------------|
| 84.4 <sup>o</sup> C at - 2081 m MSL | DST no. 1  |
| 83.3 <sup>o</sup> C at - 2062 m MSL | DST no. 2A |
| 76.8 <sup>o</sup> C at - 1882 m MSL | DST no. 3  |

These temperatures are compared with data from previous drilled wells on the Delta structure in appendix A5.

The data indicate a temperature of approx.  $74^{\circ}\text{C}$  at - 1900 m MSL and a temperature gradient of  $3.5^{\circ}\text{C}/100\text{ m}$  in the Brent formation. In the Cook member of the Dunlin formation the data indicate a temperature of approx.  $81^{\circ}\text{C}$  at - 2000 m MSL and a temperature gradient of  $3.2^{\circ}\text{C}/100\text{ m}$ .

4.6 Sampling

The surface sampling and bottom hole samples taken in well 34/10-9 are listed in appendix A6.

The analysis of the samples do not compare with data from previous drilled wells. The analysis done by Statoil Production Laboratory are listed in appendix A6.

4.7 Fracture test

After finishing bottom hole sampling on DST no. 3 a fracture test was performed. During the bullheading with water, after 45 barrels had been pumped, the BHP reached 5562 psia. This pressure was higher than the expected fracturing pressure of the formation. During the injection test the BHP steadily decreased. It is therefore believed that the formation was fractured during the bullheading at a pressure of 5562 psia. This pressure corresponds to a equivalent mudweight of 2.06 g/cc.

The data collected during the fracture test can be found in appendix A7.

Max recorded Temp. 84.4°CRemarks

The PBU no. 2 is analysed by using the maximum slope method. The initial pressure calculation is very sensitive to changes in production time and PVT data. No attempt was done to match the pressure obtained from the initial PBU by changing this data in PBU no. 2. The pressure estimated from the initial PBU is assumed to be more realistic.

A handwritten signature is written over a wavy horizontal line. Below the line, the word "Signature" is printed in a small, sans-serif font.

34/10 - 9

FORMATION INTERVAL TESTS

FIT NO 1 Sampled at 2132 m RKB

The drawdown was approximately 80 psi during sampling with final shut in of 4866 psi. Sample bled on rig. Chamber contained water.

pH = 9.0

P<sub>f</sub> = 0.25

NaCl = 17500

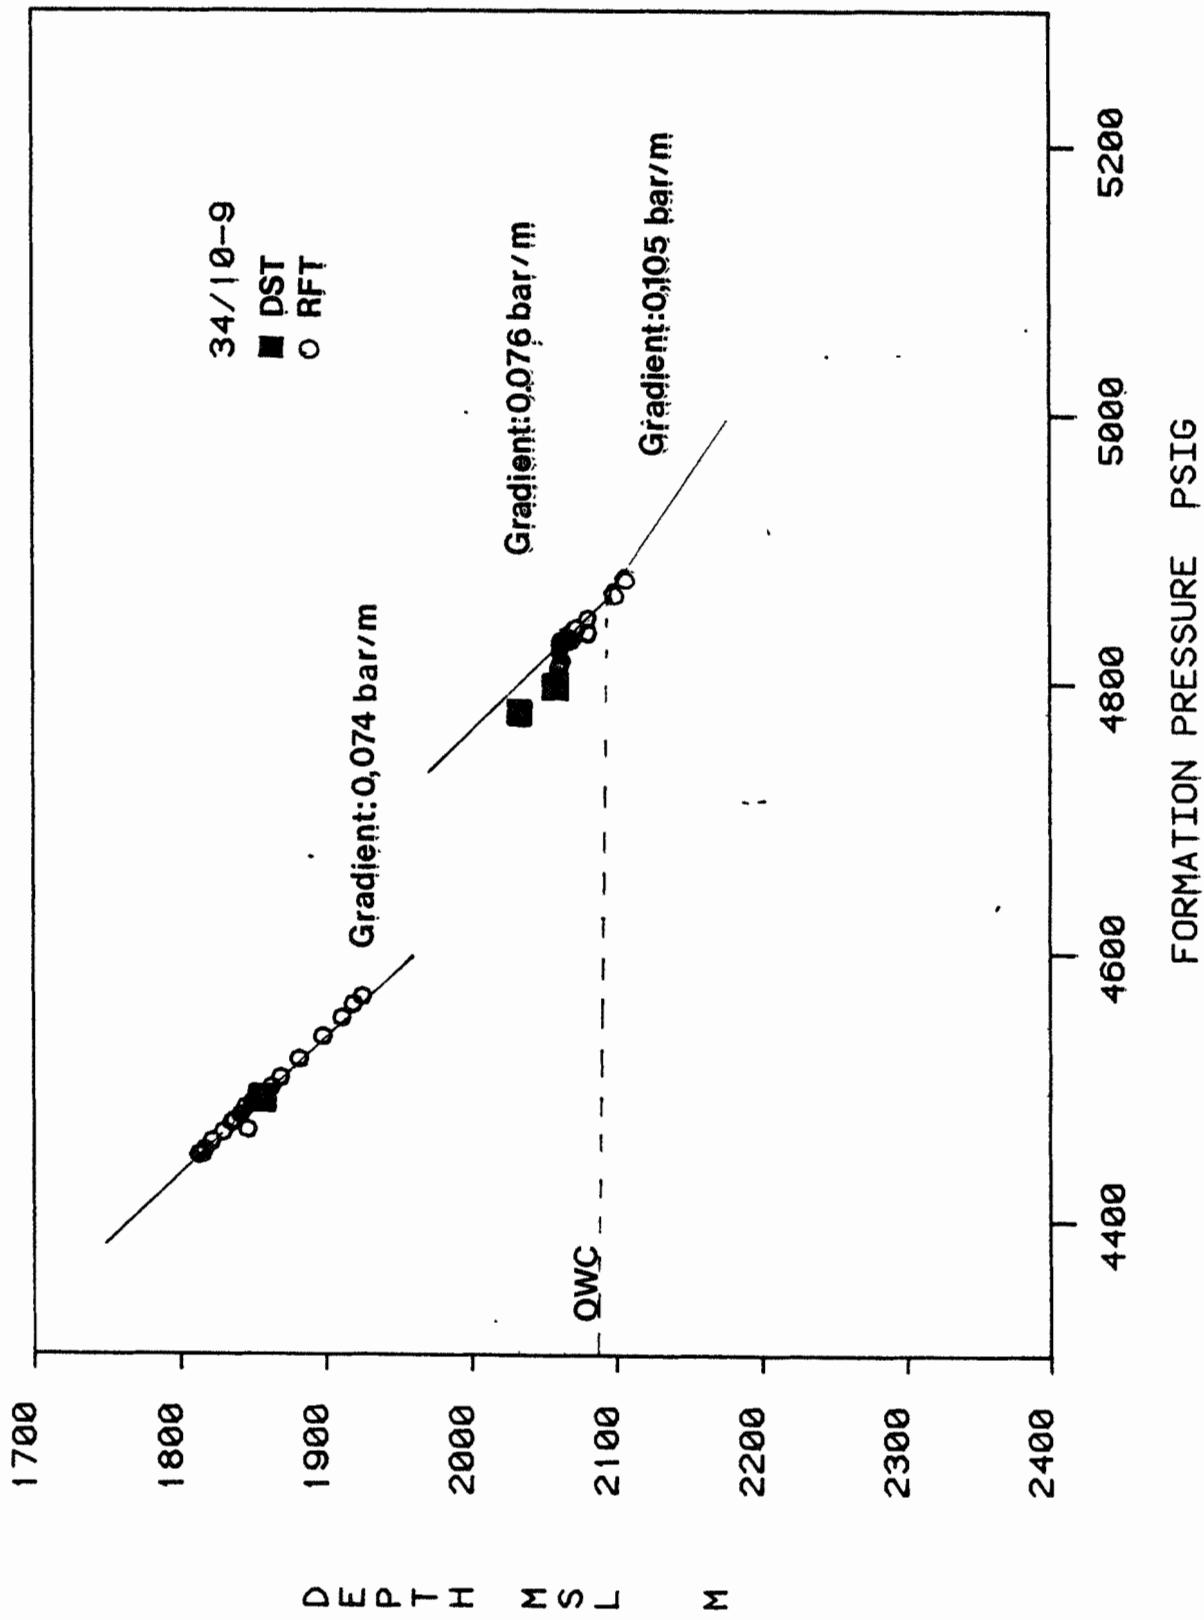

TH = 180 ppm

Ran two Sperry - Sun ganges. (SPG 113, 15 sec. mode, 10000 psi - SPG 266, 30 sec. mode 10000 psi.)

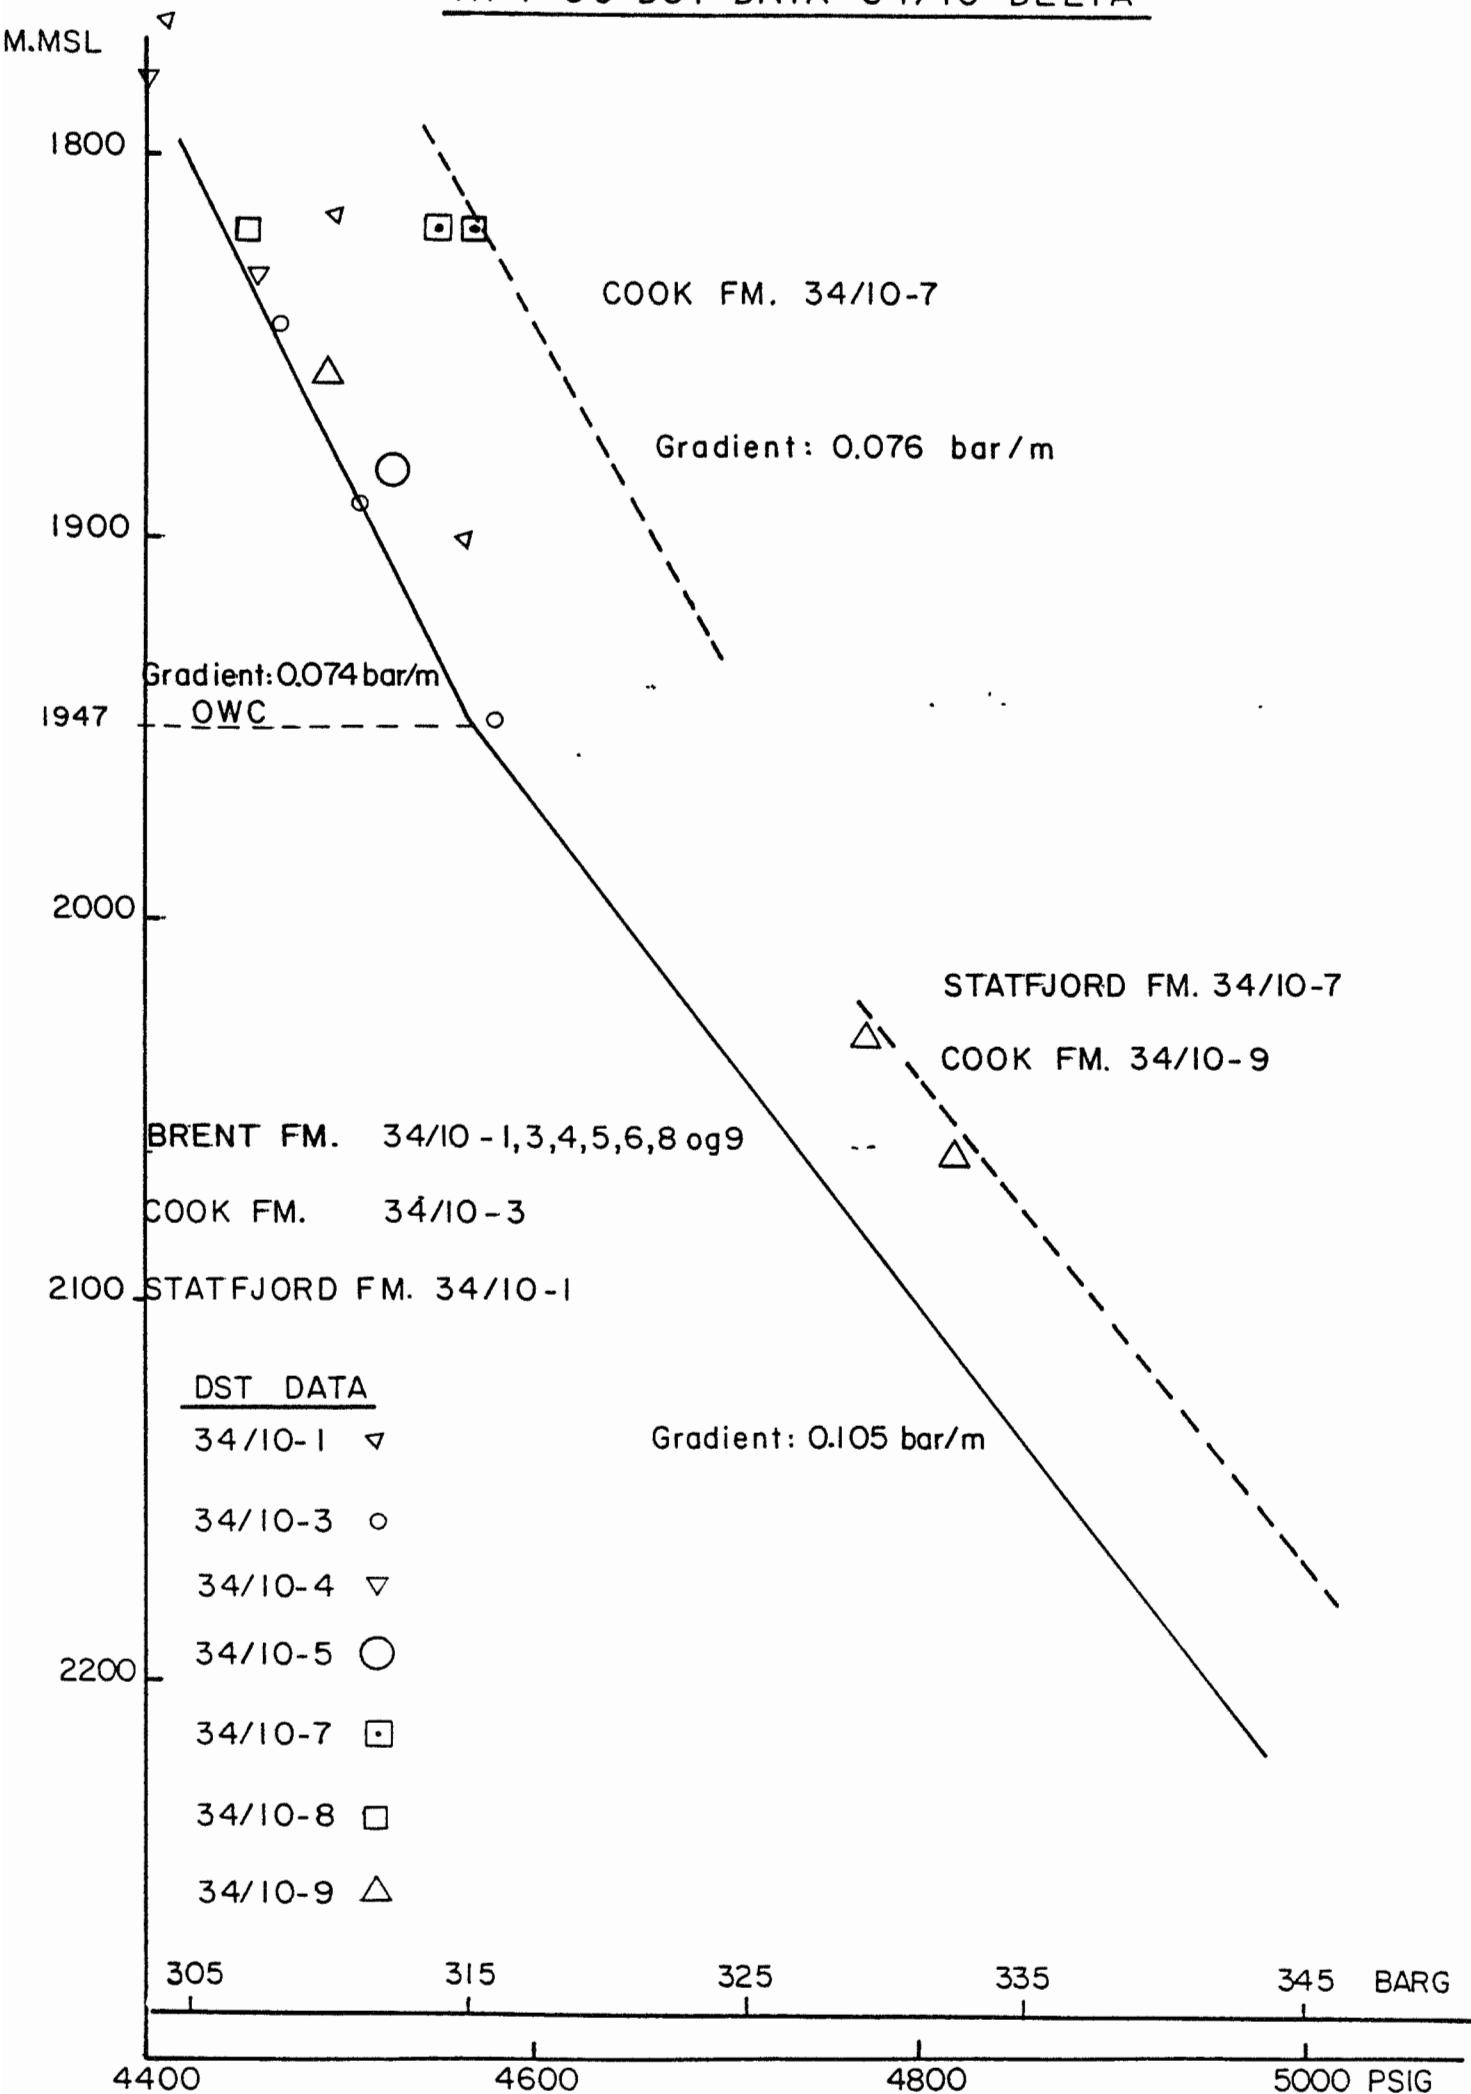

FIT NO 2 Sampled at 1840 m RKB

Segregated sample attempted with Sperry - Sun pressure recorders attached (SPG 113, 15 sec. mode, 8000 psi - SPG 266, 15 sec. mode, 8000 psi). Surface monitoring of pressure indicated drawdown, but plugging. No final buildup seen on either chamber. Gas bled off while dismounting Sperry - Sun ganges. Chambers were sealed and sent to Statoil PVT - lab.

| APPENDIX A7, Fracture test        | Page |
|-----------------------------------|------|
| Fracture test, 34/10-9, DST no. 3 | A7-2 |

FRACTURE TEST34/10-9 , DST # 3

After finishing bottomhole sampling, the well was bullheaded with water. WHP decreased during bullheading until it increased to 2800 psi after 45 barrels had been pumped. Slowed down pumprate to ~ 0.32 bbls/min, and started injection test.

See enclosed tables and plot for injection test data.

The formation was fractured at ~ 12:17 pm, after 45 barrels had been pumped. This can be seen on the pressure - time plot. The BHP has a peak of 5562 psi, which is greater than the estimated fracture pressure of 5492 psi. From then on the BHP steadily decreases. The WHP increases during the injection test due to friction loss in the tubing.

A plot of WHP versus barrels pumped can not be used, due to the effect of friction loss and the fact that the formation was fractured at the start of the injection test.

Calculated fracture gradient from maximum bottomhole pressure:  $\frac{5562 \text{ psi} \times 10}{14.5 \times .98 \times 1904} = \underline{\underline{2.06 \text{ g/cc}}}$

\*) Problems getting second pump started.

Measured time to pump 5 barrels.

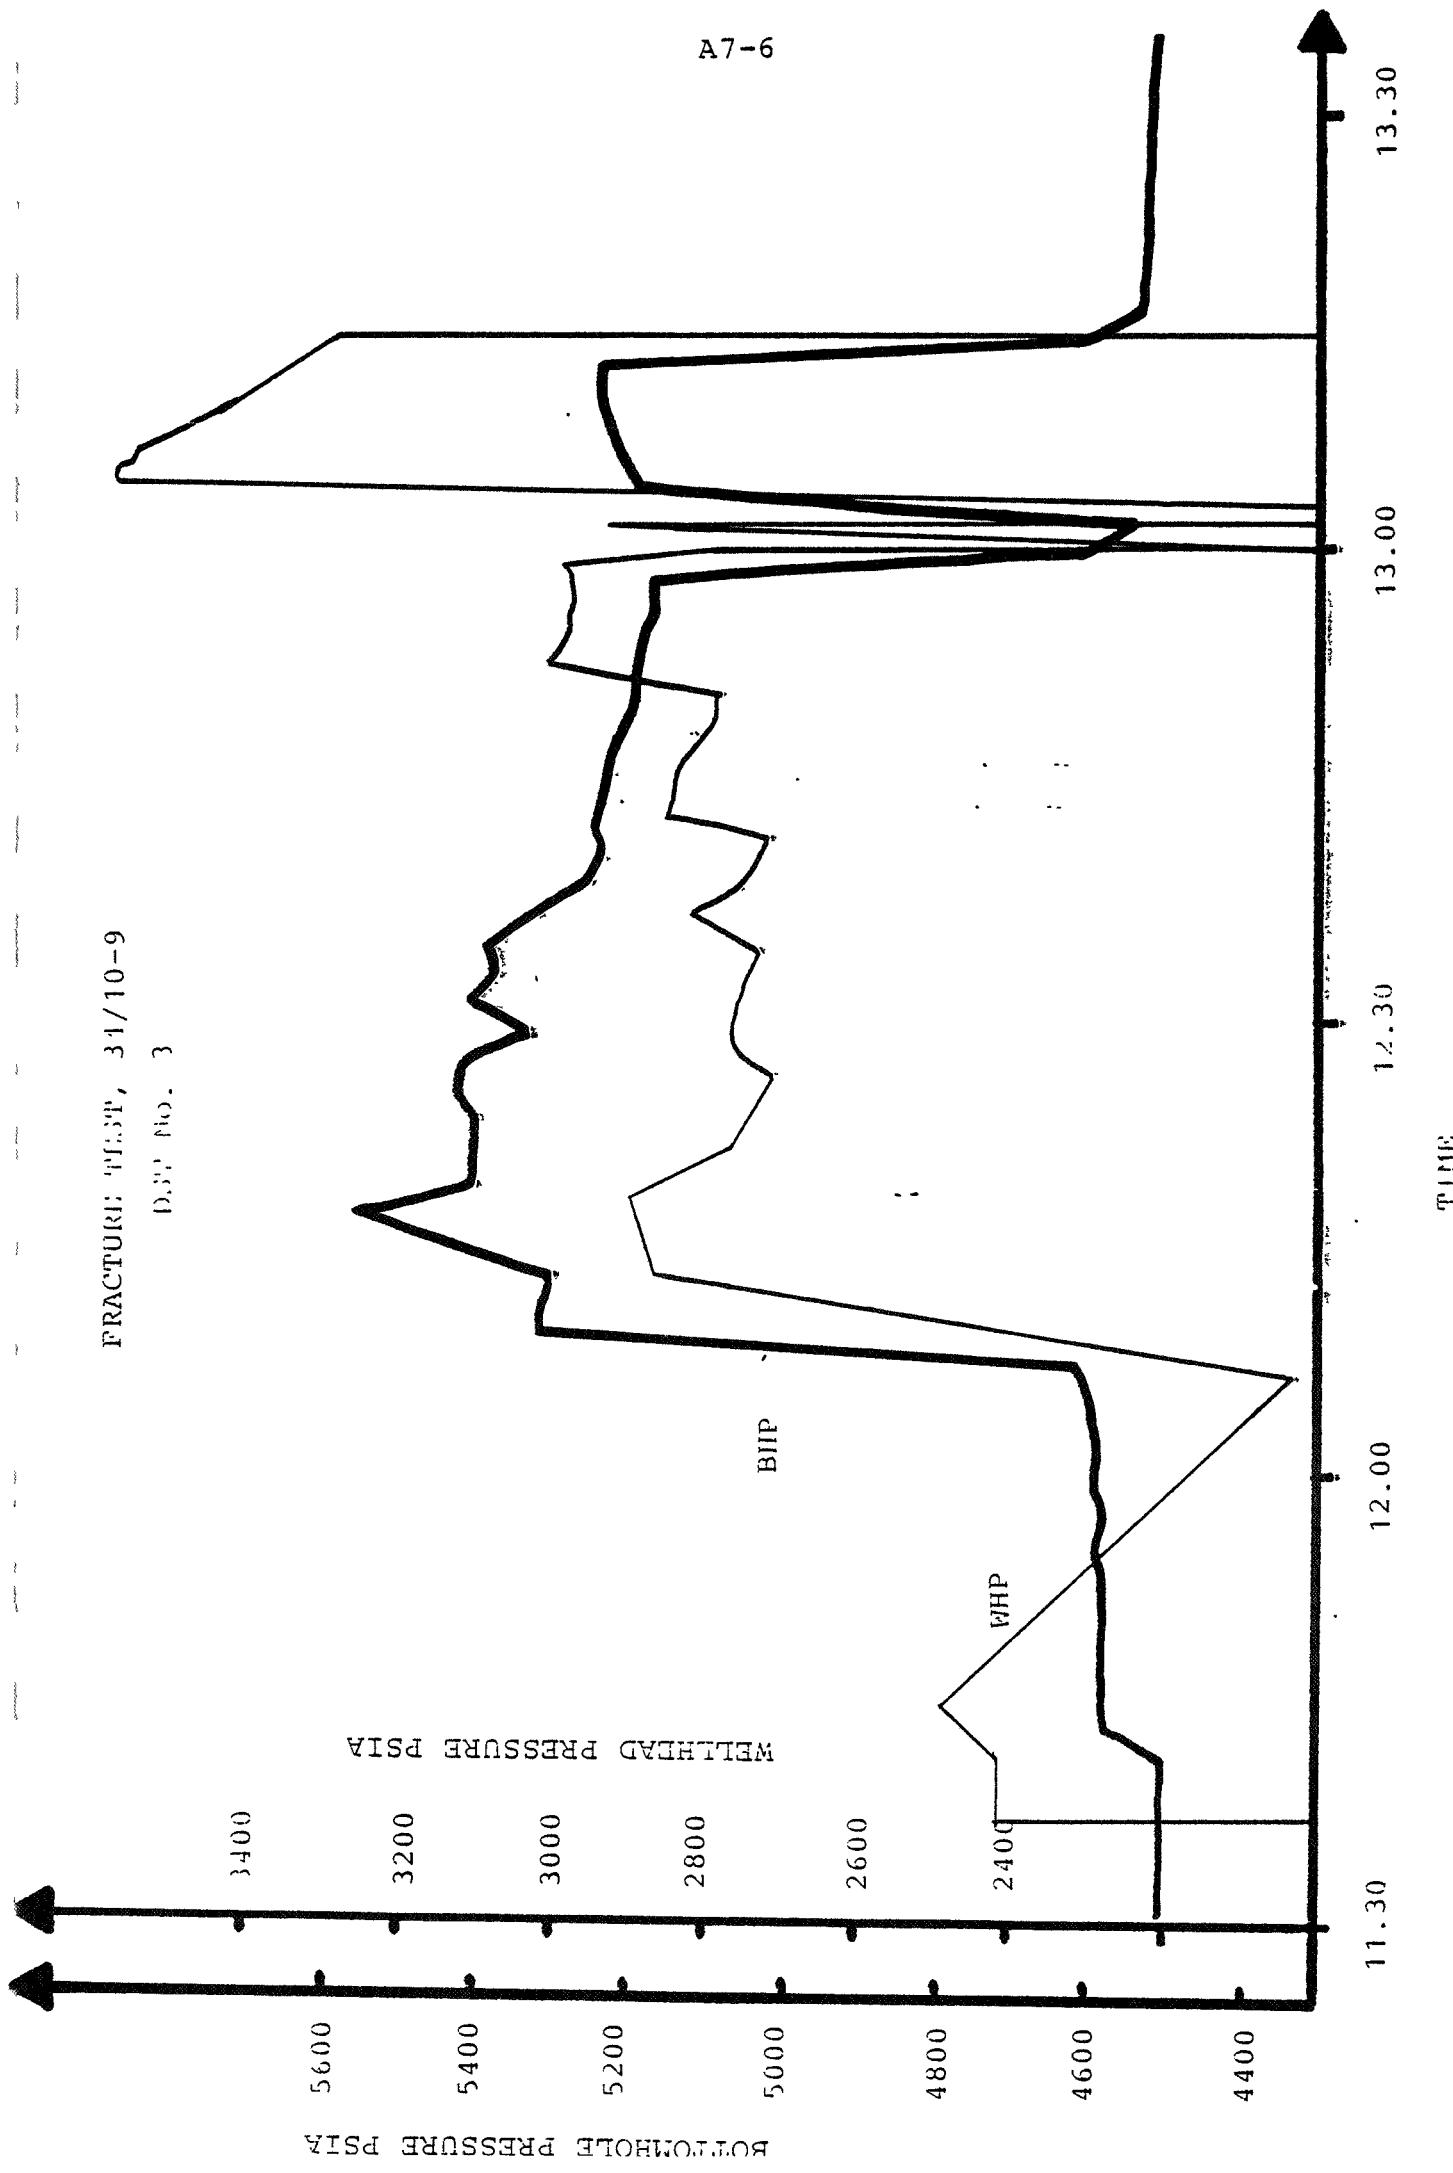

\*\*) Stage 7 lasted 5 minutes. Two individual rate measurements each gave  $\approx$  6 bbls/min.
