LIST OF CONTENTS FOR 30/9-5

Preface

Licence 104 was awarded the Statoil/Hydro/Saga/Tenneco/ Norsk Agip/DNO group in 1985 with Norsk Hydro Production A.S. as operator. The licens includes the major part of the block 30/9 on the Norwegian continental shelf. See map on page II .

The group consists of the following companies:

Den Norske Stats Oljeselskap:	50 %
Norsk Hydro Produksjon A.S:	30 %
Saga Petroleum A.S:	5 %
Tenneco:	5 %
Norsk Agip:	5 %
Det Norske Oljeselskap:	5 %

SECTION A
GEOLOGY

LIST OF CONTENT

SECTION A

1. OBJECTIVES

Well 30/9-5 is located on the "J" prospect, which is a rather flat structural feature sitting close to the western margin of the Horda Platform. The structure is bounded by Jurassic strata dipping down into the north, east and south, and by the main Horda Platform fault to the west.

The well 30/9-5 was the first well to be drilled on the Horda Platform in block 30/9. The objectives of the well were to:

- Prove possible hydrocarbon accumulation in the Etive Formation sandstones of the Brent Group.
- Improve the geological knowledge of the platform area
- verify the structural and stratigraphical interpretation of the area
- acquire input for further exploration activity in block 30/9.
- Find possible hydrocarbons in sandstones if present in the Heather-Drake- and Cook Formations.

The total depth of the well was planned at 3036 ± 100 mRKB, approximately 75 m into the Triassic Hegre Group.

2. RESULTS

The well encountered a gas bearing Cook Formation and minor amounts of gas in the Brent Group. No additional hydrocarbon bearing reservoirs were encountered by the well.

The Brent Group (2236-2253 mMD, 2222-2239 mTVD) was found severely eroded in the well, and the sands were poorly developed with a high water saturation. The net sand distribution is limited to a thin layer at the top of the formation. The rest of the formation appears to be very silty. The gross thickness is 17 m with a net pay of only 0.5 m. The average porosity (0) is 20.2% and the water saturation (Sw) 58.2%.
Cut off values were 0<12%, Vsh>40% and Sw>70%.

The Cook Formation (2447-2466 mMD, 2433-2452 mTVD) has moderately good reservoir qualities in the upper part but is silty and tight in the lower part. The gross thickness is 19 m and the net pay is 7.9 m. The average porosity is 20.4% and the water saturation 24.7%.
Cut off values were 0<15%, VSh>40% and Sw>70%.

The Statfjord Formation was encountered waterbearing at 2604 mMD (2589.5 mTVD).

Two conventional cores were cut in the well, one in the Cook Formation from 2455 m to 2473.2 mMD, and one in the Statfjord Formation from 2608 m to 2626.3 mMD.

RFT results. Two runs were performed in order to take formation pressure measurements and fluid samples. A total of 25 pressure recordings were done. Segregated samples were taken at 2452 mRKB in the Cook Formation and at 2238.5 mRKB in the Brent Group.

In the Brent Group no exact fluid gradient could be established due to a limited numbers of good measurements. However, the RFT pressures indicated the presence of gas which was verified by the fluid sample.

In the Cook Formation a gas gradient of 0.3 psi/m was obtained in the upper good sands. Low permeability and "supercharging" was experienced in the lower part of this formation.

The pore pressure in the Brent Group was found to be 1.06 rd, in the Cook Formation it was 1.11 rd, indicating no pressure communication.

The Statfjord Formation and the Hegre Groups appear to have vertical pressure communication, with a water gradient of 1.45 psi/m and a maximum pore pressure of 1.07 rd.

The RFT results are summarized in Appendix III. Full details on the RFT recordings can be studied in the separate report. "Formation Evaluation Report well 30/9-5". Core descriptions and sidewall core descriptions can be found in Appendix I and II respectively.

Note: Due to shallow gas indications on the site survey seismic the well location was moved approximately 150 m. The well was then deviated from a kick off point at 1000 m to reach the planned target. A maximum hole angle of 12.3° was obtained at approximately 1250 m, then gradually dropped back and kept around $3\text{-}4^{\circ}$ from 2000 m. At the total depth (TD) the difference between measured depth (MD) and total vertical depth (TVD) was 17 meters.

3. STRATIGRAPHY

The biostratigraphy evaluation of this well was performed by Robertson Resarch Int. Ltd., located in Wales, UK. The biostratigraphy is based on ditch cuttings. Sidewall cores were used when available. Ditch cutting samples were collected from 220 mRKB, below the 30" casing.

The diagram on page 8 shows the biostratigraphical and lithostratigraphical breakdown of this well. All depths are in mRKB. The true vertical depths (TVD) are indicated in brackets.

The first analyis were carried out on mixed sand and clays of Pleistocene age assigned to the Nordland Group. The Quaternary-Tertiary boundary is placed at 340 mRKB. The Nordland Group extends down to 815 m with the top Utsira Formation at 644 m. The top and base of the Utsira Formation are picked on the resistivity and sonic logs. On the gamma ray curve the boundaries are not so well defined.

The Nordland Group is of Pleistocene age down to 340 m and of Pliocene age down to 700 m. The Lower part is of Upper-Middle Miocene age. The Hordaland Group continues from 815 m down to 1920 m, ranging in age from Upper-Middle Miocene through Lower Eocene at base.

Top Rogaland Group and the Balder Formation is again placed on breaks on the resistivity and sonic logs at 1920 mMD (1907 mTVD). The boundary between the Balder- and the Sele Formations is well defined by the gamma ray curve. More subtle changes can be seen on logs where top Lista Formation is picked at 2018 mMD (2005 mTVD), also supported by correlation to other wells in the area. The Rogaland Group, assigned to the Upper Paleocene, extends down to 2157 m (2143 mTVD). The Montrose Group, Maureen Formation equivalent was found to be only four meters in this well (2157-2161 mMD, 2143-2147 mTVD).

The Shetland Group with a massive limestone unit at the upper part was encountered at 2161 m (2147 mTVD). The uppermost nine meters are assigned to the Lower Paleocene, Danian age. A possible unconformity at the top of the Cretaceous is indicated at 2170 m. Lithologically there was no change at this depth, but shifts can be observed on logs. The Cretaceous strata are of Maastrictian age. Another unconformity marks the base of the Cretaceous.

Below the Base Cretaceous Unconformity at 2236 m (2222 mTVD) the Middle Jurassic Brent Group was encountered as a poorly developed sandy section. The Middle Jurassic was dated possibly Middle Bajocian down to 2242 m, Middle Bajocian from 2242 m to 2248 m and Lower Bajocian down to 2260 m.

The Lower Jurassic Dunlin Group was encountered at 2253 m (2239 mTVD) with the Drake Formation extending down to 2447 m (2433 mTVD). The Drake Formation was dated Middle-Upper Toarcian dwon to 2349 m, Lower Toarcian from 2349 m to 2368 m and Upper Pleinsbachian below 2368 m.

Destinct logs breaks define the Cook Formation between 2447 m to 2466 m (2433-2452 mTVD). This formation is of Upper Pliensbachian age.

The boundary between the Burton- and Amundsen Formations is not so destinct, but subtle log shifts can be seen on the resistivity and sonic curves. The picking of this boundary is also supported by correlation to other wells. A Lower Pleinsbachian age is indicated from 2510 m down to 2577 m and Upper Sinemurian down to 2610 m.

The top of the Statfjord Formation, also well defined on logs and cuttings at 2604 m (2589.5 mTVD), is comprised of well developed sands with occasionally shale/claystone interbeds. The Statfjord Formation is generally of Lower Sinemurian age. The basal section from 2853 m is dated Hettanigian. The paleo report indicates a general Upper

Triassic age from 2875 m. The Statfjord Formation - Hegre Group boundary is placed at 2872 m (2856 mTVD), set at the base of a major sandstone section. The interval below is composed of claystones with interbeds of sands and with a mulitcoloured reddish brown colour to the claystones. This interval is probably equivalent to what has been called "Raude Member" in some wells.

The well was drilled to a total depth at 2980 mRKB (2963 mTVD). The loggers depth was 2985 mRKB.

4. LITHOSTRATIGRAPHY

This summary is based predominantly on ditch cuttings descriptions. Wirelinelogs were used for assistance in lithological interpretation, and to place formation boundaries. Sidewall cores were available from 2080 m in the Paleocene and down to T.D. in the Triassic. Two conventional cores were available, one from the Cook Formation and one from the Statfjord Formation. The boundaries between systems and series are based on the paleodating report and are not always consistent with formations and groups.

4.1 QUATERNARY (128-340 m)

NORDLAND GROUP (128-815 m)

128-219 m

The 36" hole section was drilled with returns to sea bed.

219-325 m

This interval consists of interbedded clays and sands. The clays are olive gray to olive black, soft, sticky, generally very silty and sandy and non calcareous. The sands are fine to coarse grained, occasionally pebbly, loose, angular to rounded and contain traces of glauconite, mica, shell fragments and other fossils. The sorting is generally moderate to poor.

325-340 m

The basal part of the Quarternary consists of clays which are olive gray, soft, stick, silty and sandy, carbonaceous and calcareous.

TERTIARY (340-2170 m)

NORDLAND GROUP cont.

340-644 m

The upper section of the Tertiary is lithologically a continuation of the strata above. The sections consists of clays with interbeds of sands. The clays are generally similar to those above in composition and colour but are locally also medium dark gray. The sands are ranging in grain size between fine to coarse, they are subangular to rounded and poorly to locally well sorted.

Traces of shell fragments, lignite and glauconite were seen.

Utsira Formation (644-815 m)

The Utsira Formation forms the first significant sand unit in the Tertiary interval.

The section comprises a fairly massive sand with a few claystones and siltstones below. The uppermost 40 metres show an overall fining upward trend on the logs.

The sands are made up of clear to milky quartz which are very fine to coarse with medium to coarse as the dominant grain size. The grains are generally subangular to subrounded and moderately sorted. Traces of glauconite, mica, shell fragments and pyrite occur. Traces of sandstones are also seen. The sandstones are greenish gray to olive gray in colour and are very fine to fine grained. They are friable, subrounded, argillaceous and silty and calcareous cemented with no visible porosity. The siltstones, developed as thin beds throughout the section, are olive gray to dusky yellowish brown and olive black. They are soft to friable, occasionally hard, sandy and argillaceous, very glauconitic and non to locally very calcareous. Pyrite is occasionally seen in trace amounts, and shell fragments and glauconite occur in aboundance.

The Nordland Group is of Pleistocene age down to 340 m, of Pliocene age down to 700 m and of Middle-Upper Miocene below (down to 860 m).

HORDALAND GROUP (815-1920 m, 815-1907 mTVD)

The Hordaland Group is generally a section of claystones with stringers of limestones and dolomites and with some sand and sandstones beds as the upper part. The interval is, subdivided in sections which have some characteristics in common.

815-1030 m

The upper part of the Hordaland Group makes up a claysection with some interbeds and stringers of sand and siltstone.

The clays are dusky yellowish brown and olive gray, soft to firm, in part sticky, silty and sandy, micromicaceous, locally carbonaceous, locally glauconitic, occasionally micropyritic and non to locally calcareous.

The sands are similar to those of the Utsira Formation above. Traces of sandstone which are dark grey and pinkish gray in colour, very fine to coarse grained, loose to moderately hard, subangular to rounded, calcareous cemented and with traces of glauconite are also seen.

The siltstones are olive gray and dusky yellowish brown, hard, friable, very argillaceous, sandy glauconitic, locally pyrite and very calcareous.

1013-1602 m

This interval is lithologically a continuation of the overlaying interval. However, the clays have firmed up and become claystone, and stringers of limestone are common. Sand and sandstones are now more rarely occurring.

The claystones are similar to the clays above and so are the sands. The rarely occurring sandstones are described as dusky yellowish brown and light gray to medium dark gray, very fine to medium, firm to moderately hard and locally friable. They are subangular to subrounded and poorly to moderately sorted, silty, micromicaceous, locally micropyrite, in part carbonaceous and glauconitic, and calcareous to locally kaolinitic cemented. They have no visible porosity.

The limestone are white, light gray and olive gray, soft to moderately hard, blocky, argillaceous and microcrystalline to locally crystalline.

1602-1710 m

The middle part of the Hordaland Group is again a continuation of the overlying strata, and is made up of claystones with stringers of limestones and dolomites.

The claystones have changed colour slightly and are dusky yellowish brown to brownish black and dark grey to greenish black. They are generally firm, blocky to subfissile, locally silty and rarely sandy, slightly carbonaceous and micromicaceous, rarely micropyritic and non calcareous.

The dolomite are dark to dusky yellowish brown to moderately brown, hard, blocky and microcrystalline. The limestones are similar to those above.

1710-1875 m

The lithology of this interval is still similar to above. A slight colour change of the claystone was, however, described.

The claystones have become dark greenish gray to greenish black, and olive black with traces of dusky blue green to grayish green. They are non calcareous.

The limestone, which occur in thin stringers, are light gray, soft and cryptocrystalline. Dolomites, also developed in thin stringers, are dark to pale yellowish brown, moderately hard to occasionally firm, blocky and microcrystalline.

1875-1920 m

The basal part of the Hordaland Group consists of claystones which have a dusky blue green dark greenish gray and moderately brown to reddish brown and locally very dusky red colour. They are firm to moderately hard, occasionally soft, blocky to locally subfissile, rarely silty in part slightly micromicareous and micropyritic and non to slightly calcareous.

Stringers of limestones which are light gray and pale yellowish, soft to moderately hard locally argillaceous and cryptocrystalline are occasionally developed.

The Hordaland Group was deposited in a marine shelf to upper bathyal environment.

The sediments of the Hordaland Group are of Upper-Middle age (down to 860 m), Upper-Lower Miocene (860-880 m), Upper Oligocene (880-1300 m), Lower Oligocene (1300-1620 m), Upper Middle Eocene (1620-1640 m), Middle-Lower Eocene (1640-1905 m) and of Lower Eocene age from 1905 m.

ROGALAND GROUP (1920-2161 m, 1907-2143 mTVD)

Balder Formation (1920-1969 m, 1907-1956 mTVD)

The Balder Formation is made up of claystones with a few stringers of limestones and dolomites. Tuff or tuffaceous claystone occur in trace amounts throughout the section.

The claystones are medium dark- to dark gray and brownish black, firm to moderately hard, blocky, locally subfissile, rarely micromicaceous and non calcareous.

The dolomites are dusky yellowish brown to moderately brown, hard to very hard and argillaceous.

The limestones are white to very light gray to medium dark gray, hard to very hard, micromicaceous, argillaceous and crystalline.

The tuff had a medium to dark gray and rarely grayish green colour and had locally white spects. It was partly very fine grained sandy, soft to moderately hard and non calcareous.

The depositional environment was marine outer shelf to upper bathyal.

Sele Formation (1969-2018 m, 1956-2005 mTVD)

This formation consists of claystones with stringers of limestones and dolomite. Sandstone and tuff were rarely observed also in this section.

The claystones are medium dark to dark gray and medium light to medium gray and locally grading olive black. They are generally firm to soft, locally moderately hard, locally sticky, blocky to subfissible, in part slightly silty, rarely carbonaceous and micromicaeous and non calcareous.

The sandstone which was only rarely observed was light gray to clear quartz, very fine to silt and calcareous cemented.

The limestone and dolomites are similar to those above, and so is the tuff.

The depositional environment is as for the Balder Formation.

Lista Formation (2018-2157 m, 2005-2143 mTVD)

The Lista Formation very much resembles the overlying Sele Formation. Again this is a sequence of Claystones with stringers of limestones and limestones/dolomites and traces of sand.

The claystones are medium to medium dark gray and greenish gray to dark green soft to firm, sticky, slightly silty, locally glauconitic and generally non to slightly calcareous. Locally they are very calcareous, grading to marl.

The limestones are white to very light gray, firm to hard and microcrystalline.

The limestone/dolomites are pale to dark yellowish brown and medium gray, moderately hard to very hard, argillaceous and microcrystalline.

The depositional environment is the same as for the rest of the Rogaland Group.

The Rogaland Group is of Upper Paleocene age (1915-2160 m).

MONTROSE GROUP (2157-2161 m, 2143-2147 mTVD))

Maureen Formation equivalent (2157-2161 m)

The Maureen Formation equivalent is in this well developed as a thin interval of mainly claystones overlying the limestones of the Shetland Group. The claystones are predominantly medium gray, very calcareous and else similar to those above.

The Maureen Formation eq. is assigned to the Upper Paleocene.

SHETLAND GROUP (2161-2236 m, 2147-2222 mTVD))

DANIAN (2161-2170 m)

CRETACEOUS (2170-2236 m)

UPPER CRETACEOUS (2170-2236 m)

The Shetland Group is made up of a 24 meter thick unit of limestone at the top, overlying a 37 meter thick sequence of claystones with stringers of limestones, and a 14 meter thick limestone unit at the base.

The limestones are pale yellowish brown and white to very light gray, moderately hard to locally very hard, blocky, locally glauconitic and in parts very argillaceous grading to marl.

The claystones are medium dark gray to olive gray, soft to moderately hard, blocky to fissile predominantly subfissile, micromicaceous, locally glauconitic, silty and calcareous.

The upper 9 meters of the Shetland Group are assigned to the Danian age. A possible unconformity separates the Danien from the limestones of Cretaceous age below. Lithologically the limestones above and below this possible unconformity are similar.

The depositional environment in which the Danian limestones are laid down is probably more open marine than the environment in which the Upper Paleocene claystones above were depositional. As for the Cretaceous sediments on outer shelf to upper Bathyal environment is suggested.

An unconformity and a lithology change defines the boundary between the Cretaceous and Jurassic strata.

An unconformity and a lithology change defines the boundary between the Cretaceous and Jurassic strata.

As indicated above the uppermost part of the Shetland Group is of Danian, lower Paleocene age (2160-2170 m). The remaining interval is of Maastricthian age (2170-2237 m).

JURASSIC (2236-2872 m, 2222-2856 mTVD))

MIDDLE JURASSIC (2236-2260 m)

BRENT GROUP (2236-2253 m, 2222-2238 mTVD)

Only a thin sequence of sediments assigned to the Brent Group were preserved in the well. This sequence is made up of interbedded sandstones and claystones/shales with a few stringers of limestones.

The sandstones are composed of clear to milky quartz which are ranging in grain size from very fine to coarse. They are partly loose, partly friable, locally silica cemented and moderately sorted.

The claystones/shales are dark greenish gray, olive black, dusky yellowish brown and moderately brown, firm to moderately hard, silty, micromicaceous and non calcareous.

The depositional environment is deltaic to marginal marine becoming innershelf with depth.

The Middle Jurassic sequence is dated Middle Bajocian (2237-2248 m) and Lower Bajocian (2248-2260 m).

LOWER JURASSIC (2260-2872 m)

DUNLIN GROUP (2253-2604 m, 2239-2589.5 mTVD)

Drake Formation (2253-2447 m, 2239-2433 mTVD)

The Drake Formation is a sequence of claystones with a few stringers of sandstones, limestones and marl.

The claystones are described as dusky yellowish brown and locally brownish gray, generally soft and sticky, locally firm and subfissile. They are micromicaceous, carbonaceous generally silty and non to slightly calcareous.

The sandstones consists of clear to milky quartz fine to very coarse grained, predominantly medium, loose, subangular, pyritic and moderately sorted.

The limestones are medium dark and light gray, moderately hard, in part very argillaceous grading to marl, locally sucrosic and generally microcrystalline.

The marl, which was mainly seen in the middle of this section, was pale olive gray to light gray becoming brownish gray to olive gray, generally soft and blocky, laminated and slightly silty. Locally traces of shell fragments were seen.

The Drake Formation is dated Upper-Middle Toarcian (2260-2349 m), Lower Toarcian (2349-2568 m) and Upper Pliensbachian (2368-2510 m).

Cook Formation (2447-2466 m, 2433-2452 mTVD)

The Cook Formation consists of sandstones with an interbedded siltstone/shale appearing on logs as an overall coarsening upward sequence.

The sandstones are described as being light to medium to olive gray, locally light brownish gray transparent to translucent quartz which is fine to very fine grained, subangular to rounded, slightly micraceous and moderately to well sorted.

The siltstone/shale is olive gray to olive black, friable to moderately hard, locally laminated with very fine sand, micaceous, locally pyritic and slightly calcareous.

The environment of deposition is interpreted as marginal marine, inner shelf.

The Cook Formation is of Upper Pliensbachian age.

Burton Formation (2466-2527 m, 2452-2512.5 mTVD)

The lithology of the Burton Formation is claystones with interbeds of siltstones and rarely stringers of sandstones.

The claystones are olive gray to dusky yellowish brown, soft to firm, blocky to subfissile, micromicaceous, carbonaceous and generally slightly calcareous. The claystones were locally very silty and sandy grading to siltstones. Pyrite was seen locally in trace amounts.

The siltstones were light olive gray, friable, and crumble, laminated, very argillaceous, micromicaceous and non to very slightly calcareous.

The sandstones were described as light to medium gray, olive gray to brownish gray quartz, very fine to locally medium grained, friably to moderately hard, subangular to rounded and moderately sorted. Traces of mica, carbonaceous material and glauconite were seen. The sandstones were calcareous cemented with no visible porosity.

The Burton Formation was probably laid down in a marine inner shelf environment.

This formation is of Upper Pliensbachian and Lower Pliensbachian (2510-2577 m) age.

Amundsen Formation (2527-2604 m, 2512.5-2589.5 mTVD)

The Amundsen Formation is a lithological continuation of the Burton Formation above. It is a sequence of claystones with thin beds of siltstones and stringers of limestones.

The claystones and siltstones are generally as described above. The limestones are white, medium light gray, soft, argillaceous, micraceous and silty.

The depositional environment is also as for the sediments above.

The Amundsen Formation is of Lower Pliensbachian and Upper Sinemurian (2577-2610 m) age.

Statfjord Formation (2604-2872 m, 2589.5-2956 mTVD)

The Statfjord Formation consists of predominantly sandstones with interbeds of claystones/siltstones. A few beds of coaly shale were also developed.

The sandstones are made up of quartz which are light gray to light olive gray, occasionally with light brownish gray to brownish gray stain. The grainsize ranges from fine to coarse, are angular to subrounded and poorly to moderately sorted. The sandstones are loose to friable, slightly calcarecous cemented and contain traces of coal fragments and mica. They are locally agrillaceous. The visible porosity was reported as poor to locally very good.

The claystones/siltstones are light bluish gray to light greenish gray to dusky olive gray, soft to firm, blocky, micromicaceous and non calcareous.

The coaly shales were described as dark greenish gray to brownish black, firm, angular to crumbly and locally slightly sandy, in part grading to argillaceous coal.

The depositional environment is interpreted as non marine, fluvial deltaric, lacustrine and marginal marine.

The Statfjord Formation is dated Lower Sinemurian (2610-2853 m) and Hettangian (2853-2875 m).

TRIASSIC (2872-2985 m TD, 2856-2968 mTVD)
HEGRE GROUP (2872-TD)

The Triassic sequence is made up of alternating claystones and sandstones with occasionally occurring stringers of limestone and coal.

The claystone are multicoloured light gray, dusky yellowish brown, reddish brown, moderately brown, dusky reddish gray and grayish black. They are soft to moderately hard, fissible to locally blocky, slightly micromicaceous, carbonaceous, silty and generally non calcareous.

The sandstones are very light gray clear quartz, fine to very coarse, predominantly medium, loose, angular to subrounded, poor to moderately sorted and locally calcareous cemented. Traces of mica, carbonaceous material and pyrite were occasionally seen.

The limestone were white, very light gray and grayish red, soft to moderately hard, blocky, in part brittle, locally very argillaceous and microcrystalline to crystalline.

The Coal, seen at the upper part of the section, was black and brownish black, brittle, blocky to platy and shiny.

The depositional environment was terrestrial to lacustrine and fluviale.

5. HYDROCARBON SHOWS

The evaluation of hydrocarbon shows at the wellsite was carried out in the conventional manner. The complete hydrocarbon total gas dectetor (50 units = 1%) was operational together with a gas chromatograph for automatic and continous gas analysis recorded as "ppm" by volume of C1 through C5.

Hydrocarbon shows on ditch cuttings were evaluated according to Norsk Hydro's "Wellsite geologist Manual".

5.1 GAS RECORD

217-720 m

The total amount of gas ranges from trace to 0.4% methane (C1) in this major section of the Nordland Group clays and sands. Down to 375 m the mudweight was 1.05 rd, the remaining section was drilled with a mudweight of 1.10 rd.

720-1666 m

There was only trace amounts of gas (0.01-0.06% C1) in the lower Nordland Group and the major upper part of the Hordaland Group sands and clays. The mudweight was progressively increased from 1.10-1.35 rd (1545 m) and then kept stable for the remaining section.

1666-1934 m

Total gas ranged from 0.02-2.0% C1-C2 with traces of C3-IC4. Mudweight was kept at 1.35 rd down to 1890 m where it was reduced to 1.30 rd. The section represents the bottom part of the Hordaland Group.

1934-2160 m

Total gas remained low in this interval, ranging from 0.02-0.16& mainly C1-C2, with the higher values including traces of C3-IC4 in the uppermost section. The mudweight was constant at 1.30 rd, and the section contains the Balder, Sele and Lista Formations with the additional bottom Maureen Formation Equivalent.

2160-2200 m

Total gas varied from 0.02-3.1% C1-IC4 in this limestone-dominated upper part of the Shetland Group. The mudweight was constant at 1.30 r.d.

2200-2446 m

Total gas was low, ranging from 0.03-0.2% C1-C3 in this interval displaying the lower part of the Shetland Group, the Brent Group and Drake Formation. A progressive decrease in mudweight from 1.30-1.25 rd was completed at 2390 m.

2446-2540 m

A marked increase in total gas, 0.06-6.0% C1-NC4, was recorded in this section consisting of the Cook- and the Burton Formations, and including the very upper part of the Amundsen Formation. The mudweight was kept constant at 1.25 rd.

2540-2917 m

Total gas is generally low, varying from 0.03-0.19% C1-C3 with minor trace of IC4. The section is comprised by the remaining lower part of the Amundsen Formation and all of the Statfjord Formation. Mudweight is kept constant at 1.25 rd through to TD.

2917-2985 m TD

Very low total gas was recorded from this interval, 0.01-0.04 dominantly C1 with minor traces of C2-IC4. Lithology is sands and claystones of the Hegre Group.

5.2 OIL STAIN AND FLUORESCENCE

1945-1960 mMD (1932-1947 mTVD)

There is weak shows in ditch cuttings from dolomite stringers in the Balder Formation. Locally, there is a weak direct orange flourenscence with a generally fast streaming bluish white flourescent cut. The flourescent residue is bright yellow, whereas the visible residue is ligh+ brown.

2160-2185 mMD (2146-2171 mTVD)

This interval is comprised by the Lower Palaeocnee/Upper Cretaceous massive limestones, which display a fair yellowish orange direct flourescence. There is none to a slow streaming bluish white flourescent cut, and a good slow fast streaming crush flourescent cut. A pale yellow fluorescent residue is generally present.

2235-2240 mMD (2221-2226 mTVD)

This narrow section is represented by Middle Jurassic sandstones of the Brent Group. The shows are apparently weak, with only a very weak dull yellow direct flouresence. The white-yellow flourescent cut is very weak but fast streaming, and there is no visible cut.

2447-2462.5 mMD (2433-2448.5 mTVD)

This interval is confined to the sandstones of the Cook Formation. The lower half of the interval is contained in the upper part of core no. 1. A generally good petroliferous odour is present, but no direct flourescence is seen. There is a weak to fast streaming white-yellow flourescent cut with an additional milky white crush flourescent cut.

Only a local dull brown direct fluorescence was reported from the uppermost sandstones of the Statfjord Formation. There was no flouresceing or visible cut.

6. CORING

6.1 CONVENTIONAL CORES

Only two cores were cut in this well. Core no. 1 includes the major part of the Cook Formation and the very upper part of the Burton Formation. Core no. 2 was cut in the uppermost part of the Statfjord Formation.

The depths referred to are measured depths.

Core no. 1 was cut from 2455-2473.2 m with at 95.1% or 17.3 m recovery. Predominant lithologies are shale/ siltstone with massive sandstone only in the very upper part. Locally the siltstone is gradational into fine sandstone, or it carries fine sandstone in flaser beds. Lenticular/flaser bedding and bioturbation are common sedimentary features.

Core no. 2 was cut from 2608-2626.2 m with a 100% recovery. The section is comprised by sandstones locally containing intraformational conglomerate layers and thin shale layers. Coal is present only in very minor amounts. Ripple lamination and relatively low angle cross-stratification is common throughout the cored section. Bioturbation and microfaulting are present, but of very restricted importance.

Hyrocarbon shows are only reported from the uppermost part of core no. 1, their quality is rated poor.

6.2. SIDEWALL CORES

Sidewall cores were taken from 2080 m MD in the basal part of the Palaeocen Lista Formation and down to TD. From two separate runs, a total of 71 samples were recovered out of 90 shot.

A detailed description of the sidewall cores can be studied in Appendix II.

7. WIRELINE LOGGING

The following is a summary of wireline logs run in the well 30/9-5, and provides the dates, logged intervals and run numbers of each log.

LOG	DATE	LOGGED INTERVAL	RUN NO.
ISF/LSS/GR/SP	1.6.85	126-882.4 m	1A
	14.6.85	894-1910 m	2B

8. SPECIAL STUDIES

The biostratigraphic evaluation of the well has been performed by the laboratories of Robertson Research Int. Ltd, in Wales, UK. The results of this evaluation are contained in the report:

Norsk Hydro 30/9-5
Norwegian North Sea Well
Biostratigraphy of the interval 220-2980 m T.D.

The petrophysical evaluation, and the results of RFT pressure recordings and fluid sampling carried out in the well are presented in the report:

Formation Evaluation Report
Well 30/9-5
Cretaceous, Brent Eq., Cook
Statfjord and Hegre Formations.

SECTION B
OPERATIONS

1901M

LIST OF CONTENT

SECTION B

1. LOCATION SURVEY

The site survey for the 30/9-5 location was performed by Geoteam during the period March 28 to April 9 last year. The coordinates for the well were given as:

Latitude: 60° 21' 31.5"N

Longitude: 02° 53' 26.7"E

(The exact position for the well is given in "General informations" and "Positioning and anchoring of the rig")

The survey area of approximately 4 x 4 km, was covered by 5 lines running North-South, and 29 lines running East-West. One other East-West line was run as a 18.5 km long reconnaisance profile.

Sub-seabed geology according to the survey

101 m :	Water depth(126m RKB)
101-140 m :	Layer of fine acoustically transparent sand of thickness 24 meters, overlaying a 15 meters thick layer of stiff to very stiff clay.
140-166 m :	Layer of glaciomanne clay which is thought to be overconsolidated.
166-288 m :	Argillaceous sand to a dept of 254 meters. A claybed sequence is present between 254 m and 288 m.
288-758 m :	Reflectors near the top of the Pliocene might indicate sandy formations. An intermittent reflector at 758 meters might indicate a claystone layer in Miocene.

General:

The seabed slopes 0,2° towards east, with a water depth variation of 4m within the anchor pattern (3,0 km).

The side scan sonar data indicate that the seabed consists of a featureless, fine sand.

Sand mega-ripples characterize the seabed in the western part of the survey area, while the seabed in the south west corner consist of a featureless, but harder seabed than in the rest of the survey area.

2. Positioning and anchoring of the rig

The location of the well 30/9-5 was defined as shot point 1330 on the seismic line NOD 3-84-79. The well was to be spudded within a circle of radius 50 m.

Planned position of the well:

	Geogr.	UTM
Lat:	60° 21' 31.5" N	6.691.527 mN
Long:	02° 53' 26.7" E	493.972 mE

The equipment onboard the rig for navigation and positioning was Pulse-8 while the satelite navigation system was used to establish the final coordinates in the ED 1950 Datum.

Final position of the well:

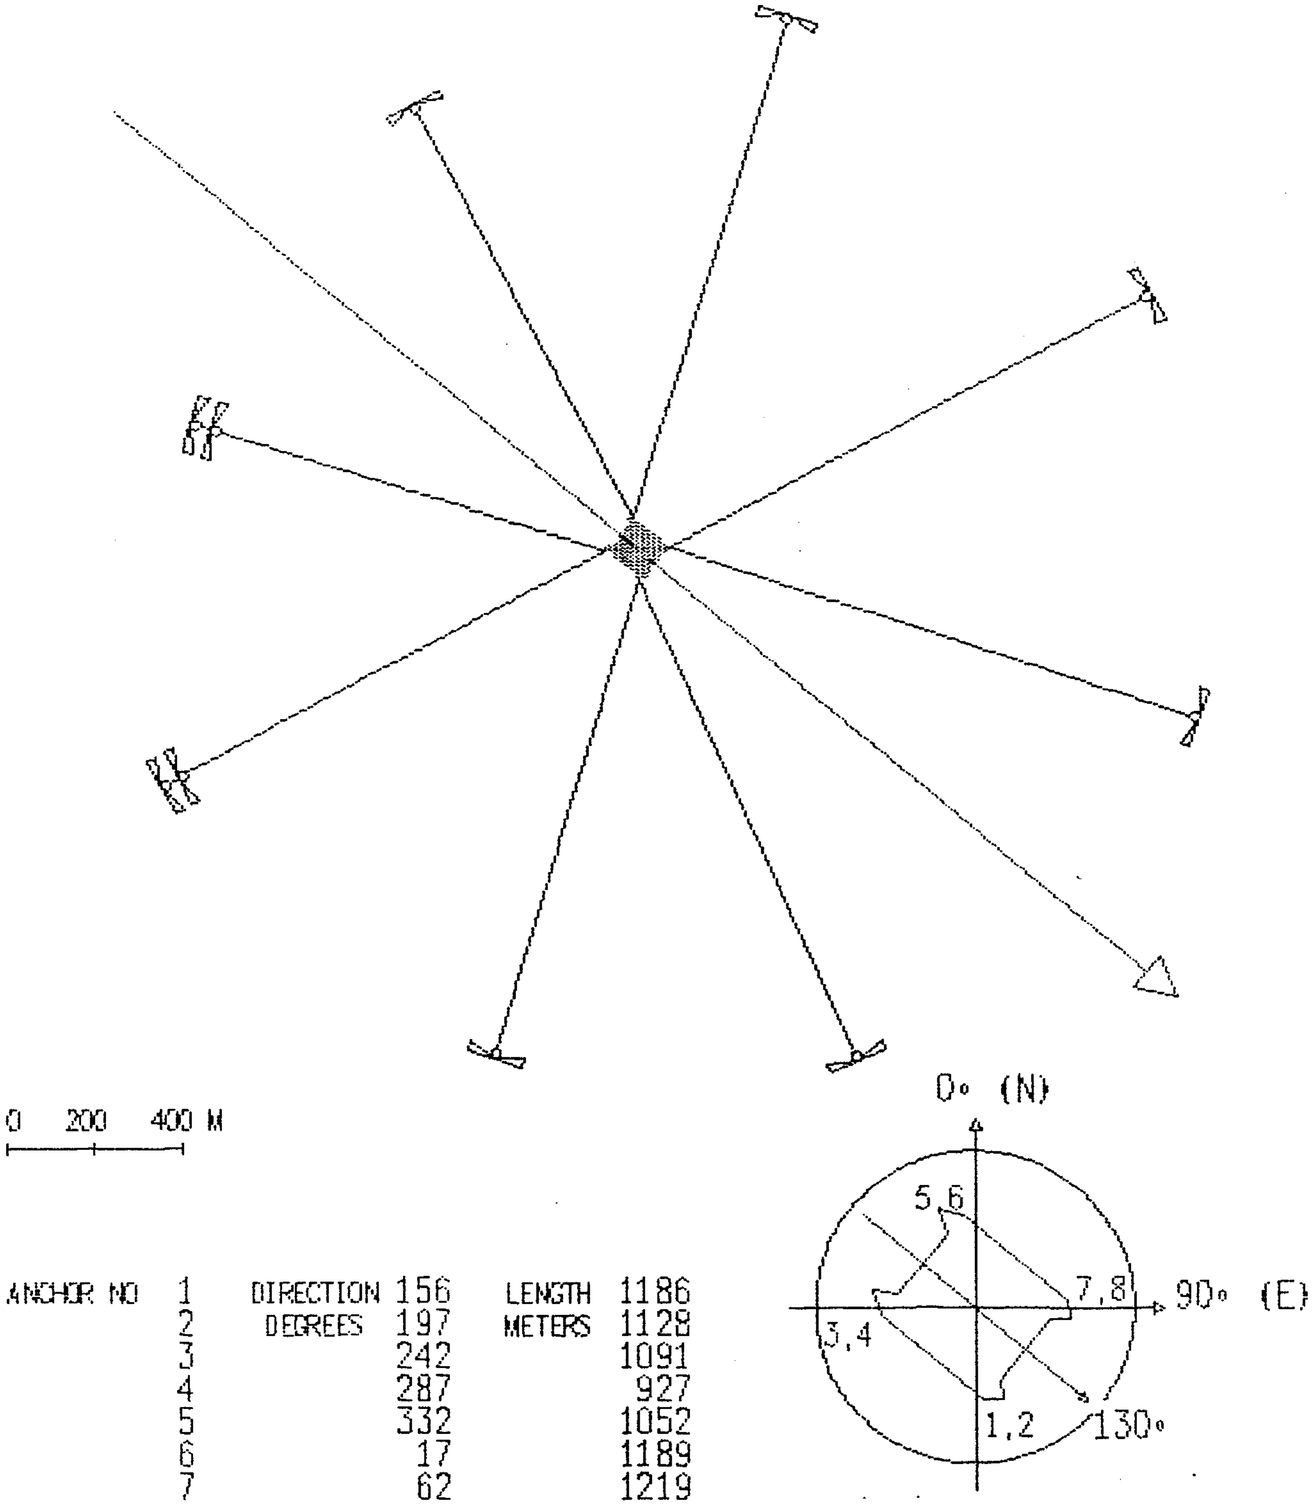
	Geogr.	UTM
Lat:	60° 21' 31.34" N	6.691.522.4 mN
Long:	02° 53' 37.09" E	494.131.4 mE

The rig heading was 130°. A 45° regular anchor pattern was used according to the operation manual.

Prior to drilling the 36" hole, the anchors were pretensioned to 445 kN.

The mooring line pattern is shown in Fig. B-1, next page.

Note: Due to shallow gas indications, the well was spudded appr. 150 m from the planned position. The hole was then deviated (kick off point at 1000 m) to reach the planned target.



ANCHOR NO	DIRECTION DEGREES	LENGTH METERS
1	156	1186
2	197	1128
3	242	1091
4	287	927
5	332	1052
6	17	1189
7	62	1219

3. OPERATION RESUME

3.1 Summary Drilling

Treasure Seeker arrived the 30/9-5 location on Mai 26th.

36" Hole Section

The well was spudded at 21.15 hours on mai 27th, 1985. The 36" hole was drilled from 128m to 219m. The 30" casing was run and landed with the shoe at 216 m and cemented back to the seabed.

26"Hole Section

The riser and the pin connector were run and the 17 1/2" pilot hole was drilled down to 885 m. ISF/LSS/GR logs were run before the pilot hole was opened to 26" using an underreamer. The 26" hole was drilled to 910 m.
The 20" casing was run and landed with the shoe at 893m and cemented back to the seabed. The BOP was run and tested prior to drill out of the 20" casing.

17 1/2" Hole section

The 17 1/2" hole was drilled to 913 m. Performed a leak-off test to 1,66 rd equivalent mud weight. The 17 1/2" hole was drilled to 1000 m. The 17 1/2" hole was drilled with turbine and kick off assembly with a building rate of 1.5°/ 30 m from 1000 m to 1214 m. Then the bottom hole assembly was changed to a locked assembly and the 17 1/2" hole was drilled to 1935 m. The hole was logged with IFS/LSS/GR/SP and LDT/GR. The 13 3/8" casing was run and landed with the shoe at 1908 m and cemented back to 450 m.
The casing and the BOP was tested and then the rig was on strike in the period 17.06 - 28.06.

12 1/4" Hole Section

The 12 1/4" hole was drilled from 1883 m to 1905 m and then displaced with NaCl-mud. The 12 1/4" hole was drilled to 1940 m where a formation integrity test to 1.65 rd equivalent mud weight was performed. The 12 1/4" hole was drilled to 2455 m where the coring started. Core no 1 was cut from 2455 m to 2471 m, and the 12 1/4" hole was drilled to 2608. Core no 2 was cut from 2608 m to 2626 m and the hole was drilled to 2980 m. The hole was logged with ISF/SONIC/GR/SP/CAL/LDT/NGT/CNL, DLL/MSFL/CAL, VSP,SHOT,RFT,CST, CBL and VDL.

The well was permanently abandoned as described in chapter 4 and fig.B-3

Treasure Seeker left the 30/9-5 location july 20th 1985.

System : Boredata Sandnes
Well: 0030/09-05

Casing Size (in):	30	20	13 3/8
Setting depth (m):	216	893	1908

Report number	Mid depth (m)	EST.PORE PRESSURE (SG)	Mud dens. (SG)	Stop time	Short Summary
1	126	0	0	02:45	Started the operation on 30/9-5.
				20:00	Treasure Seeker arrived the location 30/9-5 at 12:00 hrs.
				24:00	Ran anchor no. 1 and 5. Anchor no. 1 on bottom at 20:55 hrs.
2	126	0	1.05	17:00	Ran anchor no.8,2,4,7,6 and 3. Started to ballast and position the rig. Made up the bottom hole assembly.
				21:15	Spudded in and drilled 36" hole from 128 m to 166 m.
				23:15	Worked and reamed tight spots due to boulders from 156 m to 166 m.
				24:00	Drilled 36" hole from 166 m to 168 m. Pumped 5 m3 high viscous mud on each connection.
3	219	0	1.05	08:30	Drilled 36" hole and observed the sea floor with the R.O.V. Circulated high viscous pills on each connection.
				09:15	The pipe got stuck on the connection. Worked the pipe loose.
				10:45	Circulated and worked the pipe.
				15:45	Drilled 36" hole from 199 m to 219 m.
				16:30	Circulated the hole clean, spotted a high viscous pill in the hole and dropped the survey.
				17:30	Made a wiper trip to the sea floor, recovered the survey and ran in the hole again, had 0.5 m fill.
				17:45	Pumped 45 m3 high viscous mud.
				19:00	Pulled out of the hole.
				24:00	Positioned the permanent guide base in the moon pool. Rigged up and ran the 30" casing made up to the permanent guide base.
4	219	0	1.05	01:45	Continued running the casing. Landed the casing with the shoe at 216 m.
				02:30	Circulated with seawater.
				04:30	Rigged up and tested the cement lines. Cemented the casing as pr. program.
				08:00	Waited on the cement.
				10:00	Released the running tool and pulled out of the hole.
				22:30	Grouted the top of the 30" casing.
				23:00	Rigged up and ran the pin connector and the riser. Latched on and pulltested.
				24:00	Laid down excess drill pipe.

System : Boredata Sandnes
Well: 0030/09-05

Casing Size (in):	30	20	13 3/8
Setting depth (m):	216	893	1908

Report number	Mid depth (m)	EST.PORE PRESSURE (SG)	Mud dens. (SG)	Stop time	Short Summary
5	549	1.03	1.10	00:30	Laid down excess drill pipe.
				04:45	Made up new bottom hole assembly, ran in the hole and tagged the top of the cement at 209 m.
				06:45	Tested the flow-line seals with the diverter element in.
				07:00	Drilled the cement and the float and cleaned the rat hole.
				21:30	Drilled 17 1/2" hole and flow checked at 378 m - ok. Pumped a high viscous pill to clean the hole.
				22:15	Circulated the hole clean and dropped a survey.
				24:00	Made a wiper trip to the shoe, retrieved the survey and ran in the hole to 490 m.
6	885	1.03	1.09	00:15	Continued running in the hole to 549 m.
				12:00	Drilled 17 1/2" pilot hole from 549 m to 798 m.
				13:00	Reamed tight spots from 784 m to 798 m.
				16:45	Drilled to 885 m.
				17:30	Pumped 8 m3 high viscous mud to clean the hole.
				18:00	Spotted 107 m3 high viscous mud in the hole.
				18:15	Dropped the multishot survey.
				20:15	Pulled out of the hole to 196 m. Max overpull was 311 kN. Flow checked at 505 m. The well was static.
				20:30	Retrieved the multishot survey tool.
				21:30	Mixed high viscous mud to spot in the hole.
				21:45	Changed out hose on the block retracting system.
				22:30	Ran in the hole to 885 m.
				23:00	Spotted 111 m3 high viscous mud.
				24:00	Pulled out of the hole to 600 m.
7	885	1.03	1.09	02:00	Continued pulling out of the hole.
				06:15	Rigged up and ran ISF/LSS/GR logs.
				09:15	Laid down pipe.
				11:30	Made up the 26" bottom hole assembly and bit no. 3 and ran in the hole to 209 m.
				13:30	Underreamed the 17 1/2" pilot hole to 26" from 209 m to 233 m.
				14:00	Changed out the washpipe.
				24:00	Underreamed to 26" from 233 m to 477m.
8	897	1.03	1.20	06:30	Underreamed to 26" from 477 m to 630 m.
				09:45	Pulled out of the hole.
				12:00	Made up and tested a new underreamer and

					ran in the hole to 200 m.
				12:30	Slipped and cut the drilling line.
				13:00	Continued running in the hole to 630 m.
				22:45	Underreamed to 26" from 630 m to 885 m.
				24:00	Drilled 26" hole from 885 m to 897 m.
9	910	1.03	1.23	01:30	Continued drilling 26" hole to 907 m (bit at 910 m).
				02:45	Circulated the hole clean.
				05:15	Displaced the mud in the riser with sea water and observed the well. The well was static. Displaced back to mud and circulated.
				06:45	Pulled out of the hole to 170 m.
				07:45	Displaced the mud in the riser with sea water and observed the well. The well was static.
				09:15	Continued pulling out of the hole.
				14:30	Pulled the riser and the pin connector.
				16:45	Made up the cementing head and the 18 3/4" wellhead.
				19:30	Made up 26" bit and ran in the hole to 822 m.
				24:00	Reamed from 822 m to 910 m.
10	910	1.03	1.03	00:15	Displaced the hole with high viscous mud.
				04:00	Pulled out of the hole.
				14:15	Rigged up and ran the 20" casing. Pull tested the casing (222 kN overpull).
				16:00	Circulated and tested the cement lines to 172 bar. Pumped 17 m3 preflush.
				19:45	Mixed and pumped the cement.
				21:15	Displaced the cement with sea water. Bumped the plug and tested the casing to 69 bar.
				22:15	Pulled out of the hole with the running tool.
				23:00	Ran in the hole to 126 m with the jet sub. Washed the wellhead and pulled out of the hole.
				24:00	Rigged up to run the BOP and the riser.
11	910	1.03	1.12	03:15	Continued rigging up to run the BOP and the riser. Connected the lower marine riser package.
				03:45	Repaired the the yellow pod.
				18:00	Function tested the pods. Ran the BOP and the riser. Pressure tested the choke and kill lines to 345 bar. Positioned the rig to latch on the BOP to the well-

					head. Pull tested to 311 kN overpull. Laid down the running tools.
				24:00	Tested the BOP.
12	1000	1.03	1.15	00:45	Slipped and cut the drilling line.
				02:00	Pulled out of the hole with the test tool. Ran the seat protector.
				04:00	Pressure tested the surface equipment.
				07:30	Ran in the hole with bit no. 3(re-run 1) to 864 m.
				10:30	Drilled cement and the shoe at 893 m. Cleaned out the rat hole to 910 m.
				10:45	Drilled 17 1/2" hole to 913 m.
				12:00	Circulated to clean the hole.
				13:15	Performed a leak- off test to 1.66 rd equivalent mud weight.
				18:00	Drilled 17 1/2" hole from 913 m to 1000 m.
				19:00	Circulated and dropped the survey.
				21:15	Pulled out of the hole.
				24:00	Made up the kick off assembly. Tested the turbine and the MWD tool.
13	1188	1.03	1.17	02:30	Continued to run in the hole to 1000 m.
				14:30	Drilled 17 1/2" hole with the turbine from 1000 m to 1153 m.
				16:45	Dropped a survey, pulled out of the hole to 110 m and retrieved the survey.
				17:30	Pulled out of the hole.
				20:00	Made up bit no 5 and ran in the hole.
				20:30	Washed and reamed from 1136 m to 1153 m.
				24:00	Drilled with 17 1/2" hole from 1153 m to 1188 m.
14	1343	1.03	1.25	01:45	Drilled to 1214 m.
				02:00	Circulated to clean the hole.
				02:15	Dropped a survey.
				05:15	Pulled out of the hole, retrieved the survey and laid down the turbine.
				08:45	Made up a locked assembly and ran in the hole to 888 m.
				09:15	Slipped the drilling line.
				09:45	Ran in the hole and hit tight spot at 918 m.
				13:00	Washed and reamed from 918 m to 1214 m.
				21:30	Drilled from 1241 m to 1343 m.
				22:30	Worked the pipe in tight hole. Laid down 1 joint, washed and reamed tight hole at 1320 m.
				24:00	Made a wiper trip to 1252 m.

					bushing.
				16:45	Tested the surface equipment.
				18:00	Laid down 9 1/2" drill collars and 17 1/2" equipment.
				23:45	Made up 12 1/4" bit and new bottom hole assembly and ran in the hole. Tagged the cement at 1883 m.
				24:00	Drilled the cement from 1883 m to 1884 m.
36	2028	1.03	1.3	02:30	Drilled cement to 1905 m.
				04:00	Displaced the hole with NaCl-mud.
				05:15	Drilled the cement and the shoe and cleaned out the rat hole.
				05:45	Drilled 12 1/4" hole from 1935 m to 1940 m.
				07:15	Circulated and conditioned the mud.
				08:15	Pulled back to 1898 m and performed a formation integrity test to 1.65 rd. Ran back in the hole to 1940 m.
				10:00	Drilled 12 1/4" hole from 1940 m to 1971m.
				10:30	Circulated.
				12:45	Ran a survey on the slick line.
				14:45	Drilled 12 1/4" hole from 1971 m to 1999m.
				17:45	Dropped a survey and made a wiper trip to the shoe, had 222 kN drag. Retrieved the survey, it was a misrun.
				20:00	Drilled from 1999 m to 2028 m.
				21:15	Circulated and conditioned the mud.
				24:00	Dropped a survey and pulled out of the hole.
37	2171	1.03	1.3	07:30	Pulled out of the hole to change bit and bottom hole assembly. Picked up and tested the MWD tool and ran in the hole.
				24:00	Drilled 12 1/4" hole from 2028 m to 2171 m.
38	2250	1.03	1.29	16:00	Drilled 12 1/4" hole from 2171 m to 2235 m.
				17:30	Pumped 8 m3 high viscous-pill and circulated around.
				18:00	Made a wiper trip to the 13 3/8" casing shoe.
				18:30	Slipped the drilling line.
				18:45	Ran in the hole.
				20:30	Drilled from 2235 m to 2244 m.
				21:00	Circulated due to high gas readings.
				22:45	Circulated for samples.

System : Boredata Sandnes
Well: 0030/09-05

Casing Size (in):	30	20	13 3/8
Setting depth (m):	216	893	1908

Report number	Mid depth (m)	EST.PORE PRESSURE (SG)	Mud dens. (SG)	Stop time	Short Summary
54			1.25	04:15	Continued laying down excess drill pipe, 8" drill collars and the core barrel.
				05:15	Slipped and cut the drilling line.
				07:30	Made up bit no. 12RR, ran in the hole and tagged the cement at 1824 m.
				08:15	Closed the upper pipe ram and tested the cement plug to 148 bar for 10 min.
				14:00	Slugged the pipe, pulled out of the hole and laid down excess drill pipe.
				16:30	Ran in the hole with open ended drill pipe. Rigged up and ran in the hole with 1 11/16" casing puncher and perforated the 13 3/8" casing at 135 m. Pulled out of the hole.
				17:15	Retrieved the wearbushing.
				21:15	Ran in the hole with the cutting assembly and cut the 13 3/8" casing at 401 m. Pulled out of the hole.
				24:00	Ran in the hole with the spear assembly and retrieved the 13 3/8" casing. Laid down the same.
55			1.25	01:30	Retrieved and laid down the 13 3/8" casing.
				02:15	Ran in the hole with open ended drill pipe to 350 m.
				03:45	Mixed and pumped cement for the top plug from 350 m to 150 m. Pulled back to 140 m and reverse circulated. Displaced the riser with seawater when pulling out of the hole.
				11:30	Rigged up to pull BOP. Unlatched. Pulled the BOP and set same on the spider beams at 0830 hrs. Had lower marine riser package on the stump at 0930 hrs and the BOP on the test stump at 1030 hrs.
				16:00	Ran in hole with explosives and cut the wellhead 5 m below the seabed. Retrieved the wellhead.
				24:00	Started to deballast the rig. Picked up and removed the piggy back on anchor no.3. Pulled anchor no. 3 and 7.
56				04:15	Pulled anchor no. 2,6,8 and no. 4. Anchor no. 5 broke while being pulled.
				11:30	Repaired anchor chain no. 5.
				12:45	Pulled anchor no. 5 and no. 1. The last anchor was bolstered at 12:45 hrs.

Time distribution

The total time used to move the rig to the location, drill the well and permanently plug and abandon the well 30/9-5 was 55.42 days.

The time distribution is shown in Table B-1 and Fig B-2.

The operation can be broken down into the following main groups:

- Moving and positioning of the rig: 2.16 days
- Drilling the well to TD : 28.85 days
- Formation evaluation : 5.99 days
- Downtime : 15.99 days
- Plugging and abandonment : 2.43 days

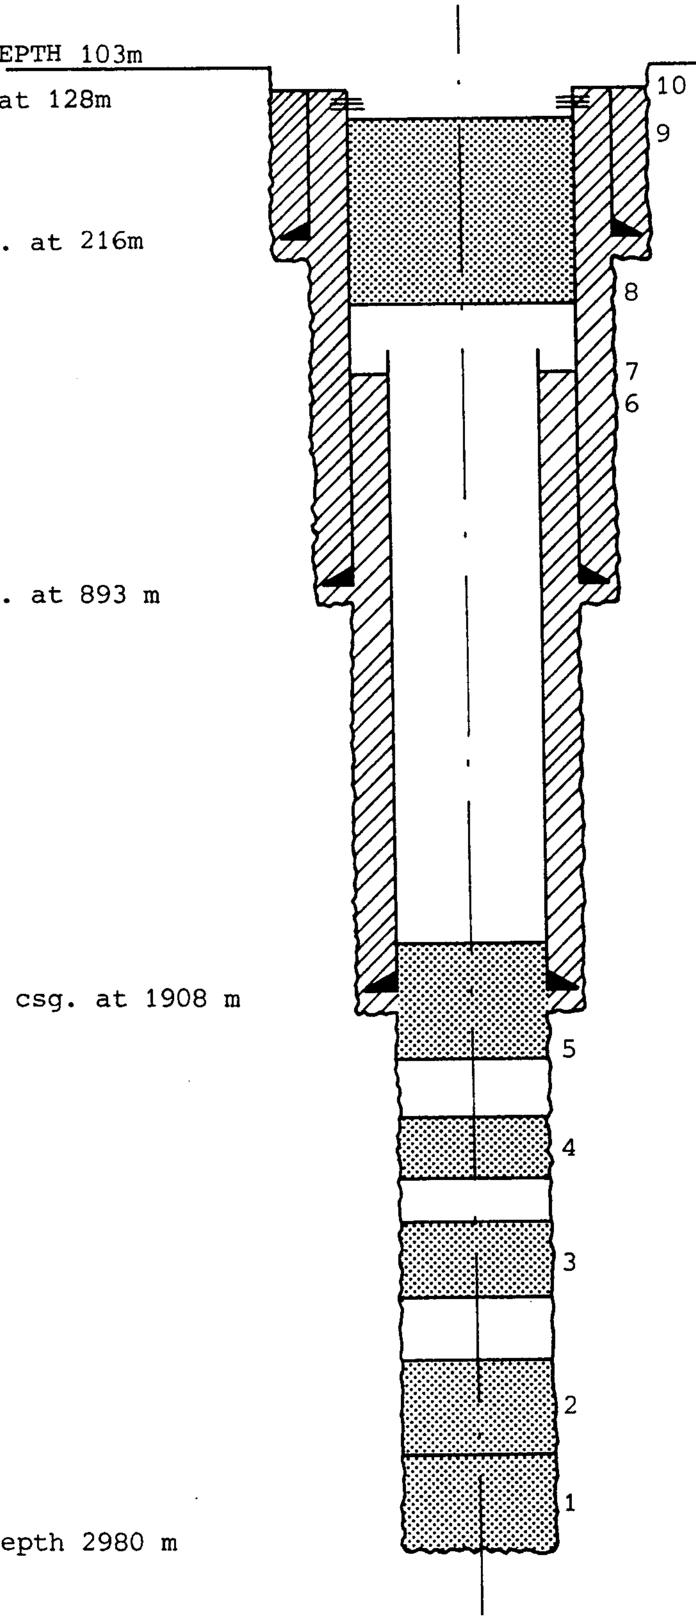
PERMANENT ABANDONMENT OF THE WELL

The permanent abandonment program is shown in fig B-3 and was carried out in the following way.

1. Set a cement plug in open hole from 2980 m to 2767 m
2. " " " 2767 m to 2555 m
3. " " " 2515 m to 2395 m
4. " " " 2305 m to 2190 m
5. Set a cement plug in open hole from 1960 m and into 13 3/8" casing to 1824 m.
6. Perforated the 13 3/8" casing at 135 m to check for gas.
   Cut the 13 3/8" casing at 401 m and retrieved it.
7. Set a cement plug from 350 m to 150 m.
8. Cut the wellhead 5 m below the seabed and retrieved it.

ALL DEPTHS REFERS TO RKB (MD)



10. 30" and 20" csg. cut at 131 m

9. Perforations at 135 m

8. Cement plug from 150 m to 350 m

7. 13 3/8" csg. cut at 401 m

6. 13 3/8" csg. cemented back to 450 m

5. Cement plug from 1960 m to 1824 m

4. Cement plug from 2190 m to 2305 m

3. Cement plug from 2395 m to 2515 m

2. Cement plug from 2767 m to 2555 m

1. Cement plug from 2980 m to 2767 m

PORE PRESSURE, FORMATION INTEGRITY, OVERBURDEN GRADIENT AND FORMATION TEMPERATURE

Pore Pressure

The pore pressure in well 30/9-5 is estimated taking into consideration the reported pore pressure, the Sonic-log and R.F.T. - logs. The sonic-log pressure has been calculated using the equivalent depth method.

From seabed to app. 1400 m MD (1394 m TVD), the Sonic-log follows a normal compaction trend, indicating a normal pore pressure of 1.03 r.d.

From app. 1400 m MD (1394 m TVD) to app. 1910 m MD (1897 m TVD), both the Sonic-log and the D_c-exponent shows a divergence from the normal trend. A similar divergence exists over the same interval in block 30/7 and the pore pressure there has been measured to be normal. It is therefore believed that the divergence from the normal is caused by lithology changes rather than increasing pore pressure.

From app. 1910 m MD (1897 m TVD) to 2166 m MD (2152,5 m TVD) the Sonic-log is showing a decrease in travel time, this is believed to be caused by lithological factors rather than a change in the formation pressure.

From 2166 m MD (2152,5 m TVD) to 2236 m MD (2222 m TVD) both the Sonic-log and the D_c-exponent is too erratic to be of any use as indicators for pore pressure work. As there is no other indications of overpressure the formation is assumed to be normally pressured.

From 2236 m MD to T.D. 2222-2963 m TVD) a number of R.F.T. measurements show pressure in the range of 1.05-1.10 r.d. as specified in the attached table. The pore pressure has been smoothed over the R.F.T. measurements in this interval.

Formation Integrity

The following table shows the formation integrity test results.

Casing size (in)	Shoe depth MD/TVD (m)	Open hole depth MD/TVD (m)	Formation integity (r.d.)
20	893/893	913/913	1.66
13.3/8	1908/1895	1940/1927	1.65

Formation temperature

The maximum recorded temperatures obtained during electric - logging have been converted to bottom-hole static formation temperature (B.H.S.T.) using the Horner-plot-technique. At 885 m there was only 1 log run, so the B.H.S.T. is obtained by adding an extra 10% to the maximum recorded value.

An estimation of the temperature gradients are listed below.

Interval (m)	Temperature gradient (DEG c/100 m)
900 - 1900	2,93
1900 - 3000	4.09

MUD REPORT

Drilling fluid used.

Hole section:	Mud:
36"	Spud mud
26"	Spud mud
17 1/2"	KCL/Polymer
12 1/4"	NaCl/Polymer

36" hole section

The 36" hole was drilled down to 219 m using seawater/high viscous s slugs. 8m^3 of high viscous mud was pumped on each connection to help cleaning the hole. At TD, the hole was displaced with 50m3 high viscous mud prior to run the casing.

Materials used in this section:

Bentonite, Caustic soda, Aluminium sterate.

26" hole section

The 26" hole was drilled down to 910 m using prehydrated bentonite/seawater. The 17 1/2" pilot hole was drilled to 885 m with at 8m3 high viscous pill on every third connection. 107m3 high viscous pill was then spotted, a wiper trip was made and another 111m3 of hivis mud was spotted before the hole was logged.

After logging, the hole was underreamed to 26" and displaced to 1,20 rd mud. The riser was then displaced to seawater and a flow check was made. The riser was then pulled and the hole was reamed with a 26" bit to 907 m with a high viscous pill on each connection. The hole was then filled with 1,23 rd mud and the 20" casing was run.

Materials used in this section:

Barite, Bentonite, Causic soda, Soda ash, AA-100 regular

17 1/2" hole section

The 17 1/2" hole was drilled to 1935 m using a KCL/polymer system. When drilling out the shoe, the mudweight was kept at 1,15 rd. At 1214 m the mudweight was increased to 1,25 rd due to sticky hole. The hole continued being tight and sticky, and the mudweight was increased to 1,30 rd at 1525 m and to 1,35 rd at 1558 m. The mud was also treated with lubricants at this stage and high viscous pills were pumped around to assist improving the hole cleaning. At 1746 m the bit balled up and detergent and nut plug was added to the mud to clean up the bit and bottom hole assembly.

After reaching TD of this section, the mud weight was cut back to 1,30 rd prior to logging. After logging, 15m3 of high viscous 1,40 rd mud was spotted on the bottom and the 13 3/8" casing was run.

Materials used in this section:

Barite, KCL brine, KCL sxs, AA-100 regular, AA-100 lovis, Anco biovis, Ancomel, Caustic soda, Drilling detergent, Defoamer, Soltex, Nut plug, Bentonite, Ancolube.

12 1/4" hole section

Prior to drilling out the casing shoe, the hole was displaced to NaCl/polymer mud. Chlorides were kept in the 55 -60000 mg/l range to optimize logging conditions. The hole was drilled to 2980 m. First wiper trip at 1999 m proved some tight spots. At 2363 the mud weight was cut to 1,25 rd and bentonite was added to improve the HTHP conditions. High viscous pills at 1.30 rd were pumped as required while drilling sandstone to give better hole cleaning. At TD a wiper trip was done without any problems. Loggs were run and the well was plugged back.

Materials used in this section:

Barite, Bentonite, Caustic, NaCl sxs, NaCl, Anco biovis, AA-100 regular, AA-100 lovis, Soda ash, Ancotemp, CMC lovis, Drispac regular, Ancolube, Drilling detergent, DF-vis(xc), Sodium bicarbonate.

Sub total		7.905
Total		57.000

The strike was effective on the "Treasure Seeker" in the period 17.06 -28.06 = 12 days delay to a total estimated cost of 6 mill. NOK.

00120

DRILLING EQUIPMENT FAILURES AND PROBLEMS

Date	Equipment	Failure/action
31.05.85	Hose on refract system	Changed out the hose.
01.06.85	Washpipe	Changed out the washpipe.
05.06.85	Yellow pod	Repaired the RBQ plate on the yellow pod.
09.06.85	Pump	Changed valve in the pump
11.06.85	Compensator	Repaired the lock bar on the compensator.
14.06.85	Mudpump	One mudpump was down.
15.06.85	Cementtank	Repaired a leak in the vent line on the cement tank.
20.07.85	Anchor chain no.5	Broke while pulling anchor.

Elevation K B:	25 m
Water Depth:	103 m MSL
Total Depth (Driller):	2980 m RKB MD (2963 m RKB TVD)
Total Depth (Logger):	2985 m » »
Formation at Total Depth:	Hegre Group

Country:	Norway
Licence:	104
Owners:	Norsk Hydro/Statoil/Saga/ Tenneco/Agip/D.N.O.
Field:	Exploration
Date Spudded:	May 27th, 1985
Reached Total Depth:	July 13th, 1985
Completed:	July 20th, 1985
Well Status:	Plugged and abandoned with gas shows in the Cook Fm. and the Brent Group.
Rig:	Treasure Seeker
Contractor:	Wilhelm Wilhelmsen
Mudlogging Company:	Exploration Logging
Logging Company:	Schlumberger
Geologists:	K. Kalgraff, K. Kjøsnes, O. Giskeødegaard, A. G. Lauvås, L. Beckman, K. Rønning, K. Kjærsrud, D. Aga, B. E. Knutsen
Prepared by:	P. A. Midtkandal, K. Kjærsrud, D. Tønseth
Date:	March, 1986.

Casing Records:

30" at 216 m
20" at 893 m
13 3/8" at 1908 m

Comments:

In order to avoid a possible shallow gas zone the well was deviated from a kick off point at 1000 m. The T.D. location is approximately 43 m north and 227 m west of the wellhead location.
