2. LITHOLOGICAL DESCRIPTION

General information:

Period are partly based on log interpretation/
Epoch correlation and partly on biostratigraphic report
Age

Lithology: Description based on the samples and core
description from the wellsite geologist on the
rig.

a) Summary

NORDLAND GROUP (123 - 1196 m KB)

The Nordland Group extends from sea bottom to the base of Miocene at 1196 m KB. Down to about 550 m the lithology is mainly interbedded sand and clay. The sand is loose, fine to medium occasionally coarse grained with some pebbles and lithic fragments. The clay is medium greyish brown, soft, silty to very silty and calcareous. Fossils, and shell fragments are common throughout the group. With the exception of the Utsira Formation, the rest of the group consists of light to medium grey, soft, silty and calcareous clay with some stringers of medium to coarse, loose and rounded sand.

Utsira Formation (884 - 1102 m KB)

The Utsira Formation consists of sand with beds of clay of variable thickness. The sand is fine to very coarse, loose, rounded and moderately sorted. The clay is medium greyish green, soft, micromicaceous and silty.

Traces of shell fragments and forams are recognized.

HORDALAND GROUP (1196 - 2299 m KB)

The Hordaland Group consists mainly of claystone which is occasionally interbedded with sandstone, especially in the upper part of Oligocene and in the Frigg formation.

Stringers of siltstone and limestone are recognized throughout the section, while stringers of dolomite are common in the lower part. The claystone is brownish grey-brownish red in the lower part of the section, soft to firm, occasionally subfissured, non to slightly calcareous, silty, micromicaceous and carbonaceous in parts. The siltstone is light grey, soft to firm, micromicaceous and carbonaceous in parts. The sandstone beds consist of clear to white quartz, very fine to medium grained, well sorted, subangular to subrounded and non calcareous. The limestone stringers are white to tan, occasionally light grey, microcrystalline and are firm to moderately hard. Finally, the dolomite stringers are buff to tan, microcrystalline and hard. Traces of tuff are seen in the lowermost part of the sequence. This tuff is light grey to greenish grey, slightly calcareous, moderately hard with black and white spots. Trace amounts of glauconite, pyrite and foraminiferas are seen throughout the sequence. Shell fragments occur in the upper part of the section.

ROGALAND GROUP (2299 - 2667 m KB)

The Rogaland Group is composed of shale and sandstone with traces of tuff in the uppermost part of the sequence. Stringers of limestone are common throughout the section.

Balder Formation (2299 - 2335 m KB)

The Balder Formation consists of a greenish grey to reddish brown, firm to moderately hard, non calcareous shale with white to tan, moderately hard, microcrystalline stringers of limestone. The tuff in this section is light to bluish grey, firm, non calcareous with white spots. Traces of pyrite are also seen.

Sele Formation (2335 - 2410 m KB)

The Sele Formation is composed of shale, one limestone layer and traces of pyrite. The shale is light to dark grey, firm to moderately hard, non calcareous, sticky in parts and occasionally micromicaceous and carbonaceous. The limestone is of the same type as described for the Balder Formation.

Lista Formation (2410 - 2547 m KB)

The Lista Formation consists of shale, sandstone beds and stringers of limestone. The shale is light to dark grey, greenish grey, firm to moderately hard, sticky in parts and non calcareous. The sandstone beds are composed of clear to white quartz grains, which are medium, occasionally fine and coarse grained, moderately sorted, subangular-subrounded, friable to hard and frequently with calcareous cement. Both the shale and the sandstone occasionally hold pyrite, glauconite and carbonaceous material. The limestone stringers are white to tan, moderately hard and microcrystalline, occasionally crystalline.

Heimdal Formation (2547 - 2596 m KB)

The Heimdal Formation is composed of sandstone of the same type as described for the Lista Formation, with a thin layer of limestone and shale in the uppermost part of the section.

Maureen Formation (2596 - 2667 m KB)

The Maureen Formation consists of interbedded sandstone and shale with limestone stringers. The sandstone is made up of clear to white quartz grains, which are medium grained, moderately sorted, subangular to subrounded, friable, occasionally hard and occasionally with calcareous cement. The shale is light greenish to dark grey, firm to moderately hard, silty in parts, non calcareous and occasionally carbonaceous. The limestone is white, soft to firm and chalky. Trace amounts of pyrite and glauconite have been observed in this section.

CHALK GROUP (2667 - 2955 m KB)

Ekofisk Formation (2667 - 2671 m KB)

The top of the Ekofisk Formation is recognized by an unconformity. The lithology in the section is made up of a white to off white, hard, brittle, crystalline to amorphous limestone, which is marly in parts.

Environment: Marine, outer shelf.

Tor Formation (2671 - 2767 m KB)

The Tor Formation consists of chalk and limestone. The chalk is white, buff, light pink brown and firm to moderately hard, occasionally very hard, while the limestone is chalky, white to cream colored, light brown, soft to hard occasionally very hard. Crystalline limestone has also been observed in this sequence.

Environment: Marine, outer shelf.

Hod Formation (2767 - 2871 m KB)

The Hod Formation is composed of limestone and some marl. It is a chalky, white to cream, occasionally light green colored, firm to hard, occasionally crystalline limestone with sections of light grey, firm to hard marl, which is grading into a limestone.

Environment: Marine, inner to outer shelf.

Plenus Marl Formation (2871 - 2924 m KB)

As the name indicates, the major constituent of the Plenus Marl Formation is marl. This light to medium grey, light pinkish grey, hard marl is interbedded with a white, cream to pink colored, microcrystalline limestone. Trace amounts of a clear, very fine to fine, subrounded, moderately sorted, calcareous cemented sandstone are also observed.

Environment: Marine, outer shelf.

Hidra Formation (2924 - 2955 m KB)

The Hidra Formation shows an almost identical lithology as the Plenus Marl Formation, i.e. marl interbedded with limestone, the difference being that the pink color of the marl, the limestone and the sandstone traces have vanished.

Environment: Marine, inner to outer shelf.

CROMER KNOLL GROUP (2955 - 3004 m KB)

Rødby Formation (2955 2980 m KB)

The Rødby Formation consists of a light to medium grey, hard marl with thin beds of a light to medium grey, reddish brown, firm to hard, calcareous to non calcareous claystone.

Environment: Marine, inner to outer shelf.

Sola Formation (2980 - 2991 m KB)

The Sola Formation is composed of interbedded marl, claystone and limestone. The marl and the claystone have the same properties as of the Rødby Formation, while the limestone is white to cream colored, microcrystalline and hard to very hard.

Valhall Formation (2991 - 3004 m KB)

The top of the Valhall Formation is shown by an unconformity. The lithology shows interbedded marl, claystone and limestone. The claystone is reddish brown, greenish grey, firm to hard, subfissured and slightly calcareous. The limestone is white, soft and chalky.

Environment: Marine, inner shelf.

HUMBER GROUP (3004 - 3070 m KB)

Kimmeridge Clay Formation (3004 - 3059 m KB)

The Kimmeridge Clay Formation exhibits two unconformities, one at the very top and one fifteen meters further down in the sequence. The lithology is composed of claystone with some limestone stringers. The claystone is greyish brown to black, firm to soft, subfissured to fissured, non calcareous, silty and carbonaceous while the limestone is white, soft and chalky.

Environment: Marine, inner shelf anaerobic/dysaerobic conditions.

Heather Formation (3059 - 3070 m KB)

The Heather Formation consists of interbedded shale and siltstone with limestone stringers. Two types of shales are observed in this section, one similar to the Kimmeridge Clay and one medium grey, hard, silty to very silty, with sand-grains. Traces of pyrite are seen in both of the different shale types.

Environment: Marine, inner shelf in upper part, marginal marine to deltaic in lower part.

BRENT GROUP (3070 - 3183 m KB)

Hugin Formation (3070 - 3127 m KB)

The Hugin Formation is composed of interbedded shale, siltstone and sandstone with layers of coal. The coal layers which are the first ones encountered in this well are black, firm to hard, vitreous, conchoidal fractured and lignitic in parts. The shale is of the grey type described for the Heather Formation, while the siltstone is dark brown, soft to friable argillaceous and pyritic. The sand is medium brown, fine to medium grained, angular to subangular, friable with dolomite - calcite cement.

Environment: Marine, marginal marine to inner shelf.

Sleipner Formation (3127 - 3183 m KB)

The Sleipner Formation consists mainly of a clear to white, fine to medium grained sandstone. It is locally silty to coarse, friable to moderately hard, subangular to rounded, well sorted, non calcareous, occasionally dolomitic cemented. Layers of coal and shale, as described for the Hugin Formation, are also observed.

Environment: Non-marine, initially fluvio-deltaic, becoming deltaic.

TRIASSIC (3183 - 3289 (TD) m KB)

The Triassic sequence is composed of interbedded sandstone and shale with greenish grey, very hard, occasionally silty dolomite stringers in the uppermost part. The sandstone consists of clear quartz grains which are frosted, fine to coarse, rounded, poorly to moderately sorted with a green and orange stain. Further down the section, the sandgrains get more angular, better sorted and also show some dolomite cement and red stains. The shale is varicolored, soft and very calcareous. One layer of white to buff, chalky, crystalline limestone is also observed in this section.

Environment: Terrestrial, lacustrine/fluviatile.
