**Beskrivelse**

## Nordmela Formation

### Name

Nordmela is a small community on the west coast of Andøya. Our use of the term corresponds to the description by Olaussen et al. (1984) and to the informal term T2-4.

### Well type section

Well [7121/5-1](#) (Statoil), coordinates 71°35'54.88"N, 21°24'21.78"E, from 2507 to 2445m. The entire formation is cored in this well ([Fig 4.48](#)).

### Well reference section

Well [7119/12-2](#) (Statoil), coordinates 71°00'51.81"N, 19°58'20.81"E, from 1719 m to 1517 m. All but the basal 31 m are cored in this well ([Fig 4.49](#)).

### Thickness

62 m in the type well and 202 m in the reference well.

### Lithology

The formation consists of interbedded siltstones, sandstones, shales and claystones with minor coals. Sandstones become more common towards the top.

### Basal Stratotype

The base is defined by a sharp increase in gamma ray response to high, irregular, patterns in contrast to the cylindrical, blocky to bell-shaped pattern of the underlying unit. This shift is accompanied by an increase in bulk density readings.

### Lateral extent and variation

Thickness variation between the type and reference wells clearly illustrates a southwest thickening wedge. This is in marked contrast to the underlying [Tubåen Formation](#). Westwards thickening may be the result of early Kimmerian subsidence over the site of the Ringvassøy-Loppa Fault Complex.

### Age

The formation extends from the Sinemurian to the late Pliensbachian in the reference area. Its top may be diachronous, younging eastwards into the Toarcian in the type section.

### Depositional environment

The formation was deposited in tidal flat to flood plain environments. Individual sandstone sequences represent estuarine and tidal channels which dissected this low-lying area.

### Source
