

General information

Lithostrat. unit	SNADD FM
NPIDID lithostrat. unit	150
Level	FORMATION
Lithostrat. unit, parent	STORFJORDEN SUBGP

Level below

Lithostrat. unit

Description

Snadd Formation

Name

From the seal species *Pusa hispida*. The present formation corresponds to unit T1-4 or Aun Formation of earlier informal terminology.

Well type section

Well [7120/12-2](#) (Norsk Hydro), coordinates 71°07'30.03 "N, 20°48'19.0"E, from 2927 m to 2354 m ([Fig 4.44](#)).

Well reference sections

Well [7120/12-1](#) (Norsk Hydro), coordinates 71°06'48.7"N, 20°45'20.1"E, from 3474 m to 2535 m.

Well [7120/9-2](#) (Norsk Hydro), coordinates 71°29'40.81"N, 20°42'05.38"E, from 3962 m to 2552 m ([Fig 4.45](#)).

Thickness

The formation thins from 1410 m in [7120/9-2](#) to 944 m in [7120/12-1](#). An apparently anomalous thin development of 573 m in [7120/12-2](#) reflects faulting out of approximately 400 m of the middle and upper parts of the unit.

Lithology

Basal grey shales coarsen up into shales with interbeds of grey siltstones and sandstones. Limestones and calcareous interbeds are relatively common in the lower and middle parts of the unit, while thin coaly lenses are developed locally further up. Distinctive dusky red-brown shales occur near the top of the unit. Lateral and vertical lithological variations may provide the basis for 2 to 4 member subdivisions or for the establishment of several formations.

Basal Stratotype

The base represents a clear log break at the base of a 60 m shale interval above the mixed lithologies of the underlying unit. This is marked on logs by a sharp increase to a more uniform response in gamma ray, interval transit time and neutron porosity readings.

Lateral extent and variation

High rates of deposition occurred throughout the area and there was little differentiation between earlier negative and positive structural elements. The unit contrasts with under- and overlying sequences in terms of palaeogeographic controls on sedimentation

patterns, perhaps reflecting updoming of northern shelf margins.

Age

A Ladinian to early Norian age is suggested. Correlations around the Ladinian/Carnian transition suggest earlier deposition of coarse elastics in central than in southern parts of the Hammerfest Basin.

Depositional environment

The Ladinian sequence represents relatively distal marine environments in all wells, following a major transgressive pulse which submerged all structural highs and platform areas in the region. Input of storm-derived silts and sands from southern sources is indicated. The Carnian is marked by large-scale progradation of deltaic systems over the entire region.

Correlation

The Snadd Formation shows great similarities in age and development to the lower and middle parts of the [Kapp Toscana Group](#) of Svalbard (the Tschermafjellet and De Geerdalen formations).
